LSASD Project ID: 19-0457

Final Report

Assessment of Resuspended Sediments as a Source of PFAS to the Upper Coosa River Basin

Conasauga, Oostanaula, & Coosa Rivers

Georgia

Project Dates: September 16th – September 18th, 2019

Final Report Approval Date: December 5th, 2019

Project Leader: Nathan Barlet
Environmental Sampling Section
Applied Science Branch

SECTION B: Project Overview & Design

B1. Introduction

The headwaters of the Coosa River Basin begin in Tennessee and the North Georgia Mountains as the Conasauga, Coosawattee, and Etowah Rivers. The confluence of the Conasauga and the Coosawattee Rivers form the Oostanaula River south of Dalton Georgia before converging with the Etowah River forming the Coosa River in Rome Georgia. The Coosa River flows west across the Alabama-Georgia state line and is then impounded in Leesburg Alabama to form Weiss Lake.

The Conasauga, Oostanaula, and Coosa Rivers have historically tested positive for the presence of per- and polyfluoroalkyl substances (PFAS) via monitoring studies conducted by the Georgia Environmental Protection Division (GAEPD). PFAS have also been detected in the receiving waters of Alabama on the Coosa River and Weiss Lake by the Alabama Department of Environmental Management (ADEM), and the U.S. EPA Region 4's Laboratory Services & Applied Science Division (LSASD).

PFAS are man-made chemicals that do not occur in nature and have been found to be persistent and accumulate in both the environment and the human body via exposure pathways such as consumption of contaminated food and drinking water. PFAS have been extensively used in industry, manufacturing of commercial products, and as a component in aqueous film forming foams (AFFF) used for firefighting. There is evidence that suggests exposure to PFAS can lead to adverse health effects and are an emerging concern to public health. PFAS is a generic nomenclature encompassing a broader array of chemicals, with the most studied being perfluorooctanoic acid (PFOA) and perfluorooctanesulfonate (PFOS). The U.S. EPA has issued a Recommended Health Advisory for drinking water of 70 ng/L (ppt) for combined concentrations of PFOA and PFOS compounds. Extensive information regarding PFAS can be found at http://www.epa.gov/pfas.

Exceedances of the U.S. EPA's Recommended Health Advisory for PFOA and PFOS have been observed at both the drinking water intakes for the City of Centre Alabama in Weiss Lake and further downstream on the Coosa River in the City of Gadsden Alabama. Data collected by ADEM from 2016 through 2019 observed elevated detections of both PFOA and PFOS in Weiss Lake and on the Coosa River (both downstream and upstream of the lake). In 2012 and 2016, elevated levels of PFOA and PFOS were detected in the receiving waters of the Oostanaula and Coosa Rivers in studies conducted by GAEPD.

The Looper's Bend land application site (LAS) operated by Dalton Utilities is located along the main stem of the Conasauga River in Dalton Georgia. Surface water samples collected by GAEPD in both 2012 and 2016 in the Conasauga River and associated tributaries draining the Looper's Bend LAS contained elevated concentrations of both PFOA and PFOS. In 2009, an analytical data report was submitted to the U.S. EPA by Dalton Utilities showing elevated levels of PFOA, PFOS, and other PFAS related compounds in groundwater, wastewater effluent, soil, and compost samples collected at the Looper's Bend LAS (MPI, 2009). Research indicates some PFAS compounds may adsorb to soils and sediments and is influenced by the presence of solid organic

carbon, and that the sorption potential tends to increase with carbon chain length and is elevated for PFOS relative to PFOA (ITRC, 2018; Anderson et al., 2016; CONCAWE, 2016). Furthermore, the adsorption of certain PFAS such as perfluoroalkyl carboxylic acids (PFCAs) (e.g. PFOA) and perfluoroalkyl sulphonic acids (PFSAs) (e.g. PFOS) to positively charged suspended particles may be an important transport pathway in surface water (CONCAWE, 2016). Background concentrations of PFAS in sediments in the Coosa River Basin downstream of Looper's Bend LAS and the potential of sediment as a source of PFOA and PFOS via resuspension and transport to receiving waters is currently unknown. The purpose of this study was to observe background concentrations and composition of PFAS in sediments and co-located surface water samples collected at spatially stratified scales in the Upper Coosa River Basin stemming from the Conasauga at Looper's Bend LAS.

B2. Methodology

Unless noted otherwise, all field activities described below were conducted in accordance with the approved Assessment of Resuspended Sediments as a Source of PFAS to the Upper Coosa River Basin Sample and Analysis Plan (SAP) (USEPA, 2019*a*), standard operating procedures and policies outlined in the Applied Science Branch Quality Assurance Project Plan (USEPA, 2018*a*), and LSASD's ISO/IEC 17025 accreditation issued by the ANSI-ASQ National Accreditation Board.

Study Area:

The study area for this project included the main stem of the Conasauga River adjacent to the Looper's Bend LAS in Dalton Georgia, the Oostanaula River from Resaca to Rome Georgia, and the receiving waters of the Coosa River from Rome Georgia to the Alabama – Georgia state line (Figure 1). A total of eight sites were assessed, which included four sites on the Conasauga River, three sites on the Oostanaula River, and one site on the Coosa River near the Alabama – Georgia state line. See Table 1 for a description and coordinates of all sites sampled in this study.

Surface water and sediment samples were collected at CRI, OOST3, and OOST2 on Monday September 16th, 2019. The remaining sites (OOST1, CONA1, CONA2, CONA3, and CONA4) were sampled on Tuesday September 17th, 2019. A new location relative to the SAP (USEPA, 2019*a*) was substituted for CONA2 due to limited access and extremely low water depths causing significant portions of the Conasauga River to be unnavigable by boat during the time of the study. The alternative location for CONA2 was sampled after significant effort by the field personnel to reach the proposed sampling location for this site at Looper's Bridge Road by boating in from downstream. The alternative sampling location for CONA2 was located approximately 6.7 river miles downstream of Looper's Bridge Road and 3.7 miles upstream from CONA3. All references to CONA2 in this report refer to the alternative location listed in Table 1.

Surface Water Sample Collection:

Surface water samples were collected at all sites in 15 mL polypropylene vials and analyzed for the 25 PFAS analytes listed in Table 2. Additional surface water samples were collected in 1-liter polyethylene containers at CONA1, CONA3, OOST3, and CRI and analyzed for total organic carbon (TOC) and total suspended solids (TSS) (Table 3). The sample container, preservation, and holding time requirements for all analytes are listed in Table 4. All surface water analyses were conducted at the Region 4 LSASD Laboratory in Athens Georgia.

An additional surface water sample was also collected at CONA1, CONA3, OOST3, and CRI and filtered through a 1.2 µm GF/C glass micro-fiber filter loaded into a polypropylene gravimetric filter to remove suspended particulate matter and analyzed for the dissolved fraction of PFAS analytes listed in Table 2. *This experimental procedure was performed outside of LSASD's ISO/IEC 17025 accreditation to provide preliminary insight into the downstream transport of PFAS associated with suspended particles and the resulting data should be used for screening purposes only.*

All surface water samples were collected in accordance with LSASD's Standard Operating Procedure for Surface Water Sampling (USEPA, 2016). Surface water samples collected at CONA1, CONA3, OOST1, OOST3, and CRI were collected via stainless-steel buckets lowered over the bridge crossings at each site, mid-stream, to a depth approximately 6-inches below the water surface and samples were then transferred into the appropriate containers for the corresponding analyses listed in Table 4. Surface water samples collected at both CONA2 and OOST2 were collected directly into the containers approximately 6-inches below the water surface from the edge of the boat while anchored at the coordinates listed in Table 1. At CONA4, the surface water sample was collected directly into the container at a depth approximately 6-inches below the water surface by wading in along the streambank facing upstream into the flow. Deviations between sampling methods conducted at the sites were due to both access and safety considerations for field personnel.

Sediment Sample Collection:

Sediment samples were collected at all sites in 50 mL polypropylene vials and analyzed for the 25 PFAS analytes listed in Table 2. Additional sediment samples were also collected in 8-oz glass containers at all sites and analyzed for total organic carbon (TOC) (Table 3). The sample container, preservation, and holding time requirements for all analytes are listed in Table 4. All sediment analyses were conducted at the Region 4 LSASD Laboratory in Athens, Georgia.

All sediment samples were collected in accordance with LSASD's Standard Operating Procedure for Sediment Sampling (USEPA, 2014). Sediment samples collected at CONA1, CONA3, OOST1, OOST3, and CRI were first collected via stainless-steel petite Ponar sediment grabs lowered over the bridge crossings at each site. Sediment samples collected at CONA2 and OOST2 were retrieved via stainless-steel petite Ponar sediment grabs from the side of a boat while anchored at the coordinates listed in Table 1. The sediment sample for CONA4 was collected by

hand with a stainless-steel spoon due to the significant presence of bedrock formations and unsafe traffic conditions on the bridge overhead. All sediment samples consisted of a composite of 3 separate grabs or a spoon full that were first homogenized in a stainless-steel bowl with a stainless-steel spoon before being transferred into the appropriate containers for the corresponding analyses listed in Table 4.

In-Situ Water Quality Field Measurements:

Surface water quality measurements of temperature, dissolved oxygen, specific conductance, turbidity, and pH were collected *in-situ* via YSI EXO1 multi-parameter data sondes at each site in accordance with LSASD's Standard Operating Procedure for *In-Situ* Water Quality Monitoring (USEPA, 2018*b*). See Table 5 for a detailed list of *in-situ* water quality parameters. Multi-parameter data sondes used to collect in-situ water quality measurements were maintained, calibrated, and verified in accordance with the LSASD Standard Operating Procedures for *In-Situ* Water Quality Monitoring (USEPA, 2018b).

Stream Flow Data & Mass Loading:

This study targeted near base-flow conditions. The maximum threshold for approximate base-flow conditions was defined as the 30-year monthly mean flow for September computed from USGS stream gage data on the Coosa River (USGS 02397000), Oostanaula River (USGS 02388500) and the Conasauga River (USGS 02387000). These threshold values were 3,145 ft^3/s, 1,447 ft^3/s, and 562 ft^3/s for the Coosa, Oostanaula, and Conasauga Rivers, respectively. These gages were monitored before and during the study to ensure flows were below the computed thresholds during sample collection.

Streamflow data was retrieved from 4 USGS gages located at or within relative proximity to CONA3 (USGS 02387000), OOST1 (USGS 02387500), OOST3 (USGS 02388500), and CRI (USGS 02397000) during the time of sample collection. USGS streamflow data associated with the sampling time was used in conjunction with detected PFAS concentrations in surface water samples collected at these 4 sites to compute instantaneous mass loading rates in units of grams per day.

SECTION C: Results & Discussion

C1: Analytical Data

Per- and Poly-Fluoroalkyl Substances (PFAS) in Surface Waters:

Surface water samples were collected at all sites listed in Table 1 and analyzed for the 25 PFAS target analytes listed in Table 2. A summary of detected PFAS in surface water samples are listed in Table 6. A total of 9 distinct PFAS compounds were detected in surface water samples collected throughout the watershed. The 9 compounds detected in surface waters in this study belong to 3 separate classes which include perfluoroalkyl carboxylic acids (PFCAs), perfluoroalkane sulfonic acids (PFSAs), and fluorotelomer sulfonates (FTS). The PFCAs detected in surface waters included the following compounds in decreasing order of carbon chain length; perfluorooctanoic acid (PFOA, C8), perfluoroheptanoic acid (PFHpA, C7), perfluorohexanoic acid (PFHxA, C6), perfluoropentanoic acid (PFPeA, C5), and perfluorobutyric acid (PFBA, C4). The PFSAs detected in surface water samples included perfluorooctanesulfonate (PFOS, C8), perfluorohexanesulfonate (PFHxS, C6) and perfluorobutanesulfonate (PFBS, C4). Additionally, the 8 carbon fluorotelomer sulfonate 6:2 FTS was detected in surface water collected on the Conasauga River at CONA3. 6:2 FTS is a transient environmental degradation product and precursor compound known to undergo aerobic biotransformation into shorter carbon chain PFCAs, primarily in the form of PFHxA and PFPeA (ITRC, 2018; Buck *et al.*, 2011). Long-chain compounds of both PFCAs and PFSAs are considered public health priorities due to their increased residence times in humans and wildlife (CONCAWE, 2016). Both PFCAs and PFSAs have been used by industry as wetting, dispersing, emulsifying, and foaming agents to produce industrial and consumer products ranging from protective coatings for fabrics, carpets, textiles, and paper; as well as formulations of insecticides and surfactants (Wang et al., 2017). The composition and classifications of PFAS detected in surface water samples are outlined in Figures 2 and 3.

There are currently no maximum contaminant levels (MCLs) established for PFAS nationally or for the state of Georgia. The U.S. EPA has issued a Lifetime Health Advisory (LHA) level of 70 ng/L or parts-per-trillion (ppt) for combined and chemical-specific concentrations of the long-chain compounds PFOA and PFOS in drinking water. Combined concentrations of PFOA and PFOS were detected in surface waters at significantly elevated levels 3 times greater than the LHA at sites located downstream of the Looper's Bend land application site on the Conasauga River (CONA1, CONA2, and CONA3) ranging from 250 – 280 ng/L. Residual combined concentrations of PFOA and PFOS above the LHA were also observed downstream in surface waters along the Oostanaula River (OOST1, OOST2, and OOST3) ranging from 72 – 153 ng/L. Neither PFOA or PFOS were detected at or above the minimum reporting limit (MRL) upstream of Looper's Bend on the Conasauga River (CONA1) or in the receiving waters of the Coosa River (CRI) near the Alabama-Georgia state line during the time of this study. The distribution and concentrations of PFOA and PFOS relative to the LHA in surface water samples are shown in Figures 4 and 5.

Surface water samples on the Conasauga River downstream of Looper's Bend (CONA2, CONA3, and CONA4) had the highest diversity of detected compounds with 8 distinct PFAS observed at

each site and ∑PFAS concentrations ranging from 931 – 1,110 ng/L. The diversity of PFAS compounds was also high in the Oostanaula River with 6 distinct PFAS detected at each site and ∑PFAS ranging from 361 – 463 ng/L. The short-chain compounds PFBS and PFPeA were the most prevalent PFAS detected throughout the watershed and were the only two compounds detected on the Conasauga River upstream of Looper's Bend (CONA1) and on the Coosa River (CRI). The prevalence of PFBS and PFPeA was also observed in a previous investigation of the receiving waters of Weiss Lake in Alabama (USEPA, 2019*b*). PFBS and PFPeA are short-chain replacements of PFOS and PFOA, respectively.

Surface water samples filtered through a 1.2µm GF/C glass microfiber filter in order to remove suspended sediments are summarized in Table 7. The percent recoveries of long-chain PFCAs, PFSAs, FTSs, and FASAs were significantly low after passing through the GF/C glass microfiber filter with an average loss of ∑PFAS of approximately 37%. This observation is consistent with recently published research from Sörengård *et al* (*in press*) which analyzed the effects of multiple filter materials on the recoveries of the 21 PFAS analyzed in their study. Due to the low recoveries and high variability between pre- and post-filter PFAS concentrations the results were deemed inconclusive. Thus, the contribution of PFAS transport associated with resuspended sediment was not quantified at this time. The filter analysis is being duplicated by LSASD personnel in order to verify the percent recoveries of PFAS analytes observed.

The "U" qualifier on tables and figures denotes that the analyte was not detected at or above the reporting limit. The "J" qualifier on tables and figures denotes that the identification of the analyte was deemed acceptable by the laboratory, but the reported value is an estimate. An accompanying "Q-2" qualifier denotes that the result was greater than the Minimum Detection Limit (MDL) but less than the MRL. The complete analytical results, MRLs, and associated qualifiers for all analyses of PFAS in surface water samples are listed in Appendix A of this report.

Per- and Poly-Fluoroalkyl Substances (PFAS) in Sediments:

Sediment samples were collected at all sites listed in Table 1 and analyzed for the 25 PFAS target analytes listed in Table 2. A summary of detected PFAS in sediment samples are listed in Table 8 and shown in Figure 6. A total of 16 distinct PFAS were detected in sediment samples collected throughout the watershed. The 16 compounds detected in sediments belong to 3 separate classes which include perfluoroalkyl carboxylic acids (PFCAs), perfluoroalkane sulfonic acids (PFSAs), and perfluoroalkane sulfonamides (FASAs). The PFCAs detected in sediments included the following compounds in decreasing order of carbon chain length; perfluorotetradecanoic acid (PFTeDA, C14), perfluorotridecanoic acid (PFTrDA, C13), perfluorododecanoic acid (PFDoA, C12), perfluoroundecanoic acid (PFUDA, C11), perfluorodecanoic acid (PFDA, C10), perfluorononanoic acid (PFNA, C9), perfluorooctanoic acid (PFOA, C8), perfluoroheptanoic acid (PFHpA, C7), perfluorohexanoic acid (PFHxA, C6), perfluoropentanoic acid (PFPeA, C5), and perfluorobutyric acid (PFBA, C4). The PFSAs detected in sediment samples included perfluorooctanesulfonate (PFOS, C8) and perfluorobutanesulfonate (PFBS, C4). Additionally, 3 FASAs were detected in sediment samples collected throughout the watershed which included perfluorooctanesulfonamide (FOSA), N-methyl perfluorooctane sulfonamido acetic acid (N-

MeFOSAA), and N-ethyl perfluorooctane sulfonamido acetic acid (N-EtFOSAA). FOSA, N-MeFOSAA, and N-EtFOSAA are transient biotransformation products of perfluorooctane sulfonamido ethanols (e.g. N-MeFOSE and N-EtFOSE) used in the production of surfactants and surface treatment products (ITRC, 2018), which have been shown to be potential precursors of both PFOS (Rhoads *et al*., 2008) and PFOA (Plumlee *et al.*, 2009) depending on the transformation pathway. The composition and distribution of PFAS detected in sediment samples are outlined in Figures 7 and 8.

The concentrations of PFAS detected in sediment samples are summarized in Table 8. PFOS was detected at elevated levels in all sediment samples ranging from 410 – 15,000 ng/kg (dry). PFOA was detected in sediments collected on the Conasauga River (CONA1, CONA2, CONA3, and CONA4) and the Oostanaula River (OOST1, OOST2, and OOST3) ranging from 91 – 1,100 ng/kg (dry). PFOA was not detected at or above the MRL in sediments collected on the Coosa River (CRI). There are currently no federal standards or criteria established for PFAS in sediments or in the state of Georgia. In April of 2019, the U.S. EPA issued draft interim recommendations for public comment to address groundwater contamination from PFOA and PFOS (USEPA, 2019*c*). The U.S. EPA's draft interim recommendations propose that a target hazard quotient (THQ) of 0.1 and target cancer risk (TR) of one-in-a-million be used to calculate Regional Screening Levels (RSLs) for soil protective of groundwater yielding values of 40 ppt for each compound (USEPA, 2019*c*). In order to determine a potential risk posed by contaminated sediments to the overlying surface waters, generic RSLs for soil protective of groundwater of 3.78E-02 µg/kg for PFOS and 1.72E-02 µg/kg for PFOA were derived from the U.S. EPA's RSL calculator (https://epa-prgs.ornl.gov/cgi-bin/chemicals/csl_search) using the proposed HQ=0.1 and TR=1.00E-06 (Appendix D). In general, the combined concentration of PFOA and PFOS as well as ∑PFAS increased with the presence of total organic carbon (TOC) outlined in Figures 9 and 10 and discussed in further detail in the following section of this report. Thus, RSLs were standardized by the site-specific fraction of organic carbon content based on the total organic carbon concentration measured in the sediment at each site in units of grams organic carbon per grams sediment (dry) (Appendix E). The concentrations of PFOA and PFOS detected in sediments with respect to both the generic and site-specific RSLs are outlined in Table 8 and Figure 11. All sediment samples with detected concentrations of PFOA were between 2 – 13 times greater than the site-specific RSLs and 5 – 64 times greater than the generic RSLs computed for this study. All sediments samples had concentrations of PFOS between 6 – 33 times greater than the site-specific RSLs and 11 – 397 times greater than the generic RSLs computed for this study. The RSLs presented in this report were calculated with the purpose of placing measured PFAS concentrations detected in sediments within a theoretical context for this study only. These RSLs are not enforceable and do not represent official policy of the U.S. EPA at the time this report was generated. The concentrations of PFOA and PFOS relative to both the generic and site-specific RSLs in sediment samples are shown in Figure 11.

Sediments collected on the Conasauga River had a diversity of detected PFAS ranging from 14 – 15 distinct compounds with a ∑PFAS ranging from 3,386 – 34,770 ng/kg (dry). The significantly elevated levels of PFAS detected at CONA4 relative to the other sites can be attributed to a substantial presence of TOC in the sample and the sediment sampling approach used at CONA4

which differed from the other sites in this study. Due to the prevalence of in-stream bedrock outcroppings and unsafe sampling conditions on the nearby bridge, sediment grabs were collected by hand with a stainless-steel spoon in areas of noticeable deposition. This method inherently biased the composite sample towards finer particles compared to the Ponar grabs used to collect sediment samples at all other sites. The diversity of PFAS detected on the Oostanaula River ranged from 12 – 15 distinct compounds with ∑PFAS ranging from 2,840 – 4,260 ng/kg (dry). A slight decrease in both the diversity of PFAS (ranging 8 – 9 distinct compounds) and ∑PFAS (ranging 1,067 – 2,020 ng/kg (dry)) was observed in sediment samples collected on the Coosa River. With the exception of CONA4, the average concentration of ∑PFAS in sediments on the Conasauga River was approximately 3,605 ng/kg (dry), only slightly higher than the average ∑PFAS of sediments collected downstream on the Oostanaula River (average ∑PFAS = 3,363 ng/kg (dry)). Generally, PFOS was the most abundant compound detected in sediments followed by the long-chain perfluorinated carboxylic acid PFDoA (C12), as seen in Figure 7.

The "U" qualifier on tables and figures denotes that the analyte was not detected at or above the reporting limit. The "J" qualifier on tables and figures denotes that the identification of the analyte was deemed acceptable by the laboratory, but the reported value is an estimate. An accompanying "Q-2" qualifier denotes that the result was greater than the Minimum Detection Limit (MDL) but less than the MRL. The "QR-2" qualifier indicates that MRL verification recovery was greater than upper control limits. The "Y-2" qualifier should accompany all data for N-EtFOSAA and PFTeDA as these analytes should be used for screening purposes only. The complete analytical results, MRLs, and associated qualifiers for all analyses of PFAS in sediment samples are listed in Appendix B of this report.

Analysis of Solids (TOC and TSS):

Sediment samples were collected at all sites and analyzed for TOC (Tables 1 and 3). A summary of solids in both surface water and sediment samples are listed in Tables 9 and 10. Sediment TOC ranged from 2,200 – 30,000 mg/kg (dry) across all sites. The resulting TOC concentrations at CONA4 were significantly higher than the rest of the samples due to a difference in sampling techniques. Sediment grabs were collected at CONA4 using a stainless-steel spoon in depositional areas causing the composite sample to be biased towards finer particulates and detritus. With the exclusion of CONA4, the computed average TOC for the Conasauga, Oostanaula, and Coosa Rivers were 4,200 mg/kg (dry), 6,133 mg/kg (dry), and 3,550 mg/kg (dry), respectively. An increase in combined concentrations of PFOA and PFOS as well as ∑PFAS in sediments with respect to the presence of TOC was observed both with and without the treatment of CONA4 as an outlier (Figures 9 and 10). The presence of organic carbon has been indicated as a significant factor in the retention of PFAS in both sediment and soil with increasing effects for long-chain PFCAs and PFSAs (ITRC, 2018; CONCAWE, 2016) and should be considered when comparing concentrations of PFAS in sediment across sites.

Additional surface water samples were collected at CONA1, CONA3, OOST3, and CRI and analyzed for both TOC and TSS (Table 9). The concentration of TOC in surface water samples

remained relatively consistent throughout the watershed, ranging from 1.5 – 2.8 mg/L across all sites. The concentration of TSS ranged from 9.1 – 29 mg/L throughout the watershed. On average, a slight increase in TSS was observed moving downstream (Table 9). Significant variability in TSS concentrations was observed on the Coosa River between duplicate samples, which is discussed in Section C4. – Data Quality.

The "J" qualifier on tables and figures denotes that the identification of the analyte was deemed acceptable by the laboratory, but the reported value is an estimate. An accompanying "Q-2" qualifier denotes that the result was greater than the MDL, but less than the MRL. The "QR-2" qualifier indicates that MRL verification recovery was greater than upper control limits. The complete analytical results, MRLs, and associated qualifiers for all analyses of solids in sediment and surface water samples are listed in Appendix C of this report.

C2. Field Measurements

In-Situ Water Quality:

Instantaneous measurements of temperature, pH, specific conductance, dissolved oxygen, and turbidity were collected *in-situ* at all sites and are summarized in Table 11. Water temperature ranged from 24.2 – 28.4°C across all sites depending on the time of day in which the measurement was collected. The pH of surface waters was observed to be relatively consistent throughout the watershed during the study period, ranging from 7.37 – 7.89 S.U. In general, the average specific conductance was higher on the Conasauga River (~246 µS/cm) compared to the receiving waters of the Oostanaula (~122 µS/cm) and Coosa River (~203 µS/cm). The measured values of dissolved oxygen ranged from 6.64 – 8.43 mg/L across all sites and was dependent on the time of day in which the measurement was collected. The lowest values of dissolved oxygen were observed in the early mornings with the highest values observed in the mid to late afternoon, consistent with diurnal cycles of photosynthesis and respiration. On average, a slight decrease in turbidity was observed between the Conasauga (~18 FNU), Oostanaula (~13 FNU), and Coosa Rivers (~9.3 FNU). No exceedances of ambient surface water quality criteria were observed during the period of study.

C3. Computations & Analyses

Mass Loading Rates:

Instantaneous mass loading rates were calculated in grams per day for all PFAS detected in surface water (6:2 FTS, PFBS, PFHpA, PFHxA, PFHxS, PFOA, PFOS, PFPeA), combined concentrations of PFOA and PFOS, and ∑PFAS for sites near USGS stream gages (CONA3, OOST1, OOST3, and CRI). Computed mass loading rates and associated surface water concentrations of PFAS are

summarized in Table 12 and Figure 4. Stream flow conditions were well below the base-flow thresholds set for this study and were approaching the 7-day/10-year low-flow (7Q10) for the stream gages on the Conasauga River (USGS 02387000) and the upper Oostanaula River (USGS 02387500) due to drought-like conditions experienced during the weeks prior to the study. The low-flow conditions limit PFAS inputs to groundwater intrusion, dissolution of PFAS adsorbed to sediments, transformation of precursor compounds within the sediment and surface waters, air deposition, and point-source discharges.

The highest concentrations of PFAS in surface water were observed on the Conasauga River (Table 6 and Figure 4). The Conasauga River at CONA3 accounted for approximately 74% of the combined PFOA and PFOS, and 49% of the ∑PFAS mass loading calculated for the headwaters of the Oostanaula River at OOST1 with a flow contribution of approximately 19%. Except for the short-chain PFBS, concentrations of all other PFAS compounds flowing from the Conasauga River were diluted after the confluence with the Coosawattee River (Figure 2). The flowrate of the Oostanaula increased by approximately 13% from the headwaters at OOST1 in Resaca Georgia and OOST3, upstream of the confluence with the Etowah River in Rome Georgia. Mass loadings calculated at OOST3 are largely attributed to upstream PFAS inputs with mass loadings at OOST1 accounting for approximately 61% and 71% of combined PFOA and PFOS, and ∑PFAS flux at OOST3, respectively. An increase in concentrations of both short and long-chain PFAS between OOST1 and OOST3 was observed. A significant increase in the concentration of PFOS was also observed at OOST2 downstream of Calhoun Georgia. The mass loading loss observed between OOST3 on the Oostanaula River and CRI on the Coosa River can be attributed to dilution of the PFAS compounds below the MDL making a mass balance difficult to attain.

PFAS Class and Functional Groups in Sediment and Surface Water

PFAS detected in sediment and surface waters were classified by both the functional group (*i.e.* PFCAs, PFSAs, FTSs, or FASAs) and carbon chain-length class (*i.e.* short-chain or long-chain) as defined in ITRC (2018) classifications are summarized in Table 13 and results are shown in Figures 3 and 8. In general, surface water samples were mainly comprised of both short-chain PFCAs (ranging 22 – 38%) and short-chain PFSAs (ranging 30 – 68%) throughout the watershed. Moderate levels of long-chain PFCAs (ranging 9 – 15%) and long-chain PFSAs (ranging 9 – 24%) were also detected on the Conasauga River below Loopers Bend (CONA2, CONA3, and CONA4) and along the Oostanaula River (OOST1, OOST2, and OOST3). No long-chain PFAS were detected in the water column upstream of Looper's Bend (CONA1) or in the receiving waters of the Coosa River (CRI). The fluorotelomer 6:2 FTS was also detected at CONA3 comprising only 3% of the total PFAS composition. 6:2 FTS is a potential precursor of short-chain PFCAs, primarily in the form of PFHxA and PFPeA (ITRC, 2018; Buck *et al.*, 2011).

Conversely, sediment samples were primarily dominated by both long-chain PFCAs (ranging 41 – 56%) and long-chain PFSAs (ranging 13 – 40%) across all sites. Moderate levels of both short-chain PFCAs (ranging 2 – 25%) and short-chain PFSAs (ranging 3 – 7%) were also detected in all sediment samples except for the Coosa River (CRI) in which no short-chain PFAS were observed. Furthermore, moderate levels of FASAs were also detected in all sediment samples collected

downstream of Looper's Bend (ranging 8 – 22%) with a minor composition of FASAs of approximately 1% observed upstream of Looper's Bend at CONA1. FASAs such as FOSA, N-MeFOSAA, and N-EtFOSAA have been shown to be potential precursors of both PFOS (ITRC, 2018; Rhoads *et al*, 2008) and PFOA (Plumlee *et al*, 2009).

The partitioning of long-chain PFAS to sediments and short-chain PFAS to the water column supports both theoretical expectations outlined in guidance documents (ITRC, 2018; CONCAWE, 2016) and environmental observations made in previous watershed-scale studies (Zhao *et al*, 2016). The partitioning of long-chain compounds to the solid phase was observed in this study in which the most downstream site on the Coosa River (CRI) had sediment completely devoid of short-chain PFAS while the overlying surface water was solely comprised of short-chain compounds. A study conducted by Zhao *et al*. (2016) on the Yellow River in China, observed further significant partitioning of long-chain PFAS in the water column to suspended particulate matter indicating the transport of suspended sediments as a major transport mechanism for long-chain PFAS to receiving waters. The contribution of resuspended sediments to the transport of long-chain PFAS was not quantified in this study due to low percent recoveries of PFAS target analytes and high variability of PFAS filtrate data discussed in section C1: Analytical Data of this report, and may warrant further investigation.

ITRC (2018) and CONCAWE (2016) also suggest that PFSAs tend to undergo greater partitioning to the sediment compared to PFCAs of the same carbon chain-length. In this study, an opposite effect was observed in which PFCAs were generally more abundant than PFSAs of a similar class in sediments and the composition of PFSAs were similar or greater than PFCAs in surface water. Thus, an organic carbon partition coefficient was calculated for each PFAS analyte with detectable concentrations in co-located sediment and surface water samples using the following equation:

$$K_{oc} = \frac{\left({}^{C_s}/_{C_w}\right)}{f_{oc}}$$

Where:

$K_{oc} = Organic\ Carbon\ Partition\ Coefficient$

$C_s = Concentration\ of\ PFAS\ analyte\ detected\ in\ sediment\ [ng/kg\ (dry)]$

$C_w = Concentration\ of\ PFAS\ analyte\ detected\ in\ surface\ water\ [ng/L]$

$f_{oc} = Fraction\ of\ Organic\ Carbon\ in\ Sediment\ [g\ Organic\ Carbon/g\ sediment]$

The logarithm of K_{oc} was calculated for PFBS, PFPeA, PFHxA, PFHpA, PFOA, and PFOS and plotted with respect to the carbon chain-length for each analyte shown in Figure 12. Figure 12 shows that the potential for sediment partitioning for the PFSAs (PFBS and PFOS) increased with carbon chain-length and that PFOS (C8, PFSA) did indeed have a higher sediment partitioning

distribution than PFOA (C8, PFCA) of the same carbon chain-length. In conditions of steady-state equilibrium an increase in the log K_{oc} as carbon chain-length increased would also be expected for the PFCAs (PFPeA, PFHxA, PFHpA, and PFOA). The non-linear relationship between the organic carbon partition coefficients for the PFCAs may in part be due to the transformation of precursors that include short-chain PFCAs as a terminal endpoint in the degradation pathway, such as 6:2 FTS which was detected at CONA3. More information is needed regarding the composition of PFAS sources throughout the watershed in order to determine the availability of PFSAs with respect to PFCAs and potential precursors of either functional group in order to further understand the distributions observed in the environment.

C4. Data Quality

Equipment Decontamination & Preparation:

All sampling containers were certified and managed in accordance with the LSASD Standard Operating Procedure for Equipment Inventory and Management (USEPA, 2017*a*). Equipment used for collecting samples to be analyzed for PFAS (i.e. polypropylene gravity filters, stainless-steel forceps, buckets, spoons, bowls, and petite Ponars) were washed using Luminox® in warm tap water, rinsed with PFAS-free water, air-dried on clean plastic sheets and sealed in clean plastic in preparation for field use. Personnel were required to wear clean nitrile gloves during all processes of cleaning, handling, and packaging equipment. PFAS-free water was certified to be PFAS target analyte free and supplied by the LSASD laboratory in a clean HDPE container. Equipment rinse blank quality control samples were collected after the decontamination process for each type of equipment and for each lot of nitrile gloves used for sampling and submitted to the LSASD laboratory for analysis of PFAS target analytes for verification before field use. No PFAS target analytes were detected at or above the MRLs for any equipment rinse blank quality control samples and were therefore deemed acceptable within the scope of this study (Appendix A).

Field Sampling Quality Controls:

Surface water and sediment samples collected for PFAS analysis were sampled via a trace level sampling technique to avoid cross-contamination of PFAS surface water samples due to sample collection and handling. This process required two field personnel for PFAS sample collection. A designated sampler handled the sample media and sample container only. A second designee operated sampling equipment and assisted with sample container packaging and labeling. Sampling equipment known or suspected to contain PFAS was avoided during sampling activities. Quality control samples which included field equipment rinse blanks, field blanks, and trip blanks were collected to account for the potential of cross-contamination. Additional quality control samples such as temperature blanks, field duplicates and matrix spike/matrix spike duplicates were

collected in accordance with the LSASD Standard Operating Procedure for Field Sampling Quality Control (USEPA, 2017b).

Field equipment rinse blank quality control samples were collected by rinsing equipment (i.e. polypropylene gravity filters, stainless-steel forceps, buckets, spoons, bowls, and petite Ponars) with PFAS-free water in the field, to evaluate PFAS inputs due to equipment decontamination and reuse in the field following the decontamination procedure outlined in the previous section. Field blank quality control samples were also collected by transferring PFAS-free water into 15mL polypropylene vials in the field to evaluate the trace level sampling technique used for PFAS sample collection. Additionally, a trip blank quality control sample containing PFAS-free water provided by the LSASD laboratory was stored in the sample cooler containing samples collected for PFAS analysis, to account for PFAS inputs during sample storage and transport. No PFAS target analytes were detected at or above the MRLs for any field quality control samples and were therefore deemed acceptable for the scope of this study (Appendix A).

Temperature blanks were placed inside each sample cooler and measured upon arrival to the LSASD laboratory. Temperature blanks accompanying equipment rinse blank samples collected before the commencement of field activities received by the lab on September 11, 2019 were recorded at 3.5°C. The temperature blank stored with the field samples submitted to the lab on September 18, 2019 was recorded at 1.2°C. Both temperature blanks were below the 4.0°C threshold and deemed acceptable by the LSASD laboratory.

A duplicate sample was collected on the Coosa River (CRI) and submitted to the LSASD laboratory for analysis of all analytes targeted for this study (Tables 2 and 3). The duplicate results for all detected analytes along with the calculated relative percent differences (RPDs) are listed in Table 13.

An additional field quality control sample containing PFAS-free water spiked with approximately 400 – 450 ng/L of each PFAS target analyte listed in Table 2 was provided by the LSASD laboratory in a 50 mL polypropylene tube. This sample was filtered through a 1.2 µm GF/C glass microfiber filter placed in a polypropylene gravity filter apparatus to determine the percent recovery of PFAS analytes associated with the filtration technique used to collect filtered samples. A filter blank sample was also collected by rinsing a clean GF/C glass microfiber filter and polypropylene gravity filter apparatus with PFAS-free water supplied by the LSASD laboratory. No PFAS target analytes were detected in the filter blank sample at or above the MRLs. The percent recoveries of PFAS target analytes associated with the spiked field quality control sample are summarized in Table 7.

In-Situ Water Quality Calibration & Verification:

The multi-parameter data sonde used to collect *in-situ* water quality measurements was maintained, calibrated, and verified in accordance with the LSASD Standard Operating Procedures for *In-Situ* Water Quality Monitoring (USEPA, 2018*b*). Calibrations and end-check verifications performed on all parameters measured for the duration of the study were within the acceptable

ranges in accordance with LSASD's Calibration and End-Check Acceptance Criteria (SESDFORM-060-R0).

USGS Stream Gage Data:

Streamflow data measured, stored, and managed by the U.S. Geological Survey (USGS) was used to calculate instantaneous mass loadings of PFAS analytes summarized in Table 12. Stream gage IDs and the dates and times of the streamflow measurement corresponding to sample collection (± 15 min) are listed in Table 12. All streamflow data was retrieved at www.waterdata.usgs.gov. USGS streamflow data was classified as provisional at the time of retrieval and calculations are subject to revision until they have been thoroughly reviewed and receive final approval in accordance with USGS quality assurance policies and procedures.

C5. Conclusions

A total of 9-distinct compounds of PFAS were positively identified in surface water samples collected from 8 sites located throughout the Conasauga, Oostanaula, and Coosa River watersheds. Sites located along the Conasauga River downstream of Looper's Bend LAS had both the highest diversity of compounds and ∑PFAS concentrations. The composition of PFAS in surface waters was generally dominated by short-chain compounds with PFBS and PFPeA being the most prevalent in liquid phase throughout the watershed. Both PFBS and PFPeA were also found in a previous study to be the most prevalent compounds in the receiving waters of Weiss Lake in Alabama. The diversity of PFAS was found to be greater in sediment samples collected from the same 8 sites containing a total of 16-distinct compounds. The diversity and concentration of ∑PFAS observed in sediments was found to be relatively consistent along the Conasauga and Oostanaula Rivers. In general, sediments consisted primarily of long-chain compounds with sediments collected from the most downstream site on the Coosa River being solely comprised of long-chain PFAS and sulfonamide precursors. The retention of PFAS compounds in sediment was found to be significantly affected by the presence of total organic carbon, carbon chain-length of PFAS analytes, and functional group classification (*i.e.* PFSA vs PFCA). Thus, these parameters should be considered when evaluating the distribution of PFAS at the watershed scale.

Combined concentrations of PFOA and PFOS (ranging from 250 – 280 ng/L) were detected in surface water samples at levels 3 times greater than the EPA's lifetime health advisory (LHA) of 70 ng/L on the Conasauga River below Looper's Bend LAS. Residual combined concentrations of PFOA and PFOS (ranging from 72 – 153 ng/L) were also detected at or above the LHA of 70 ng/L at all sites along the Oostanaula River. Neither PFOA or PFOS were detected at or above the MRL on the Conasauga River upstream of Looper's Bend or in the receiving waters of the Coosa River during the study period. All sediment samples collected throughout the watershed contained PFOS concentrations (ranging from 410 – 15,000 ng/kg (dry)) above the generic and organic carbon corrected RSLs calculated for this study. Similarly, all sites except for the Coosa River, had

sediments with PFOA concentrations (91 – 1100 ng/kg (dry)) above both the generic and organic carbon corrected RSLs. Sediments collected on the Coosa river did not contain detectable levels of PFOA.

The Conasauga River contributed the majority of instantaneous mass loadings of combined PFOA and PFOS (~74%) as well as ∑PFAS (~49%) to the headwaters of the Oostanaula River comprising only 19% of the total streamflow. An increase in about 13% of the total streamflow was observed along the Oostanaula River from Resaca to Rome, Georgia. Despite the increase in flow, the residual PFAS concentrations in the Oostanaula headwaters accounted for approximately 61% and 71% of the downstream mass loadings of combined PFOA and PFOS, and ∑PFAS, respectively. A loss in mass was observed on the Coosa River due to the dilution of PFAS analytes below detectable levels. Low flows and drought-like conditions preceding the study limits PFAS sources to groundwater intrusion, contaminated sediments, transformation of undetected precursors, air deposition, and point-source discharges throughout the watershed, with a significant proportion originating from the Conasauga River. This study has found that the transport of both surface water and sediments contaminated with PFAS from the Coosa River Basin present significant inputs into the receiving waters of Weiss Lake. Background concentrations of PFAS associated with Weiss Lake sediments are currently unknown. The presence of long-chain PFAS, particularly PFOS, is Weiss Lake sediments is probable.

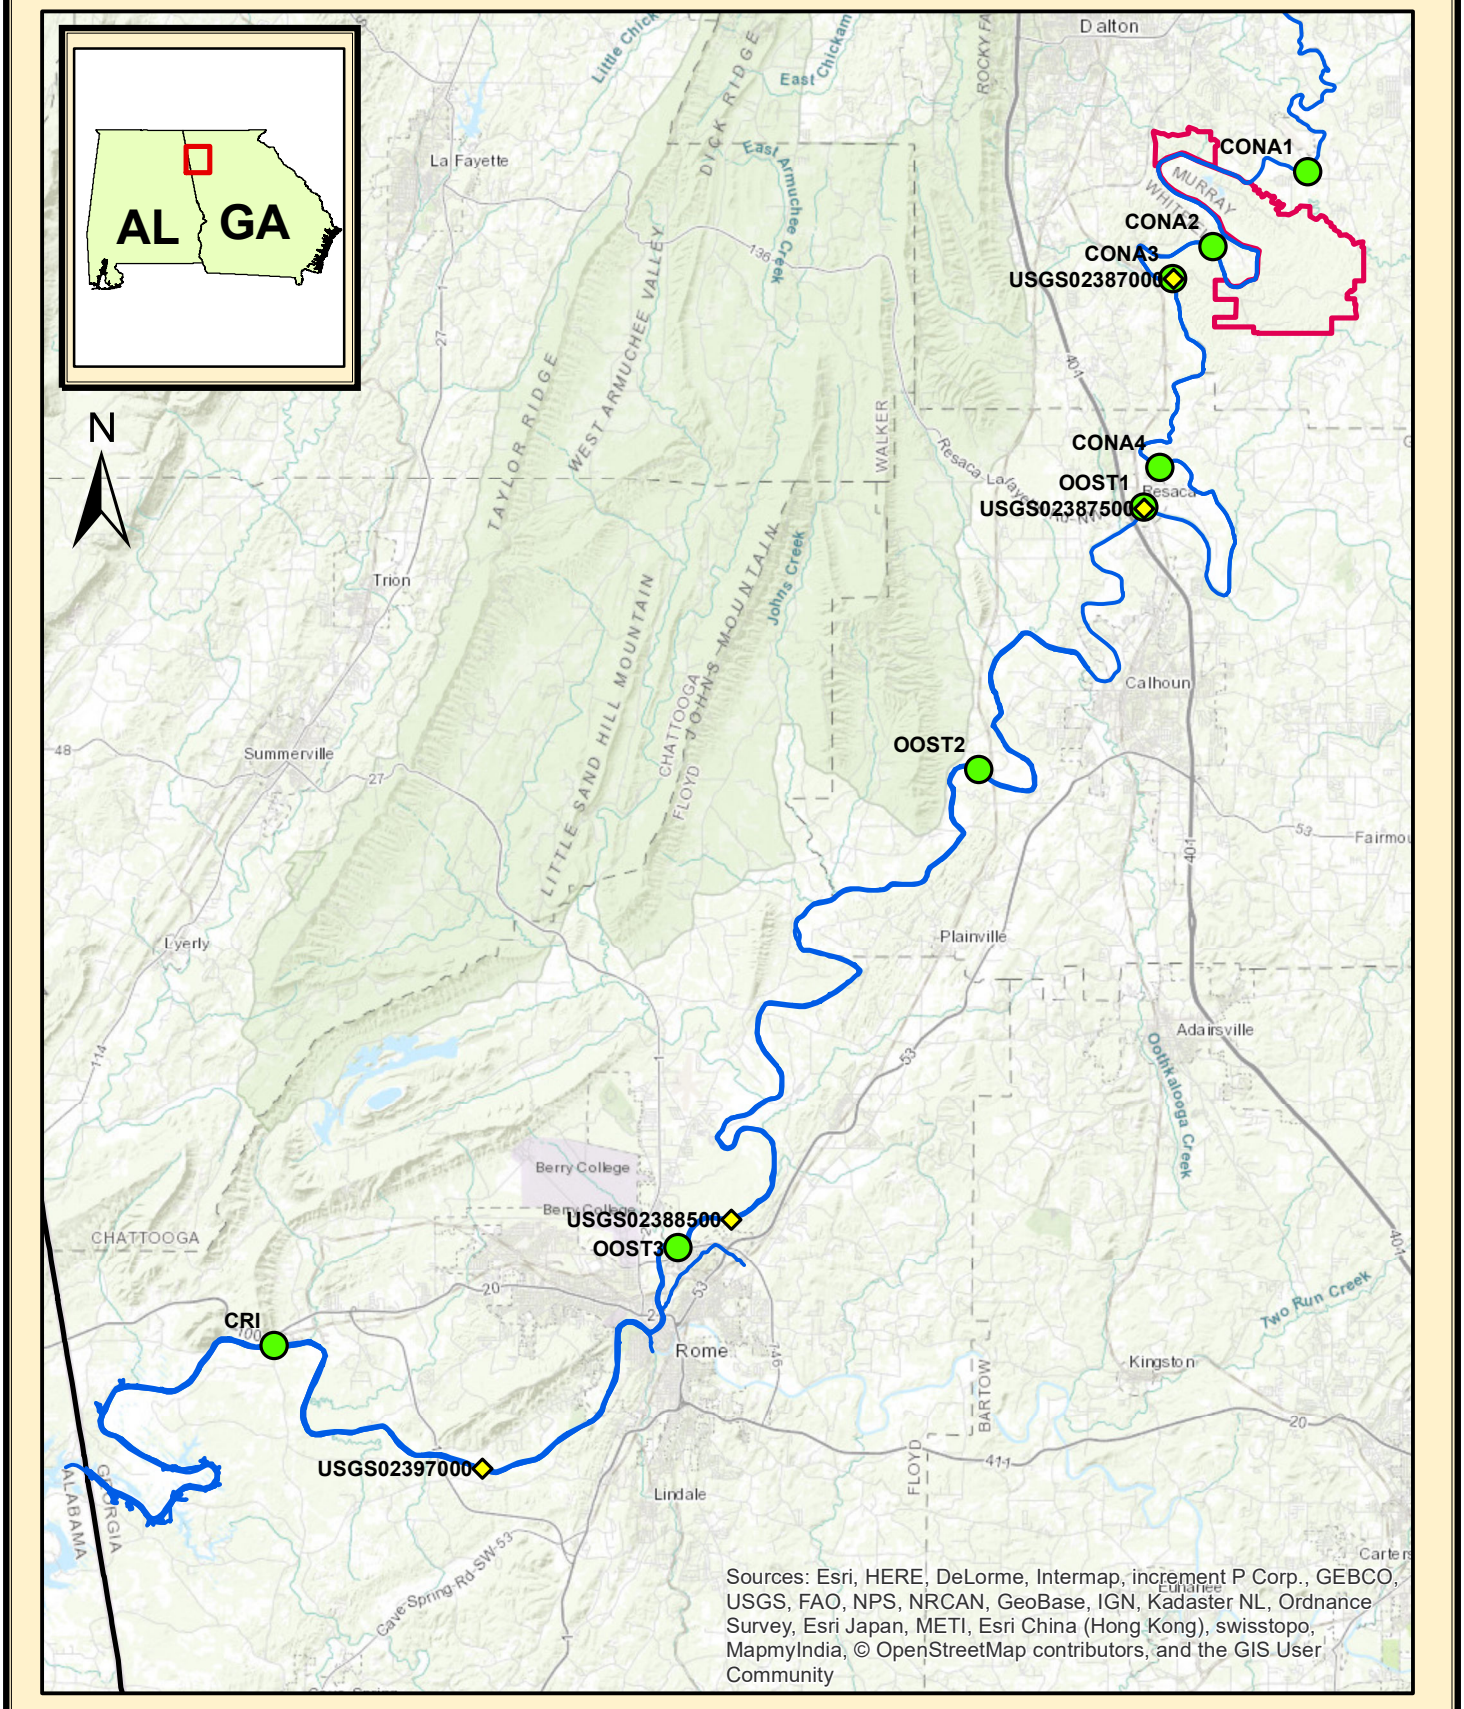
Summary Figures

Figure 1: Site Map



EPA

PFAS Sediment Screening:

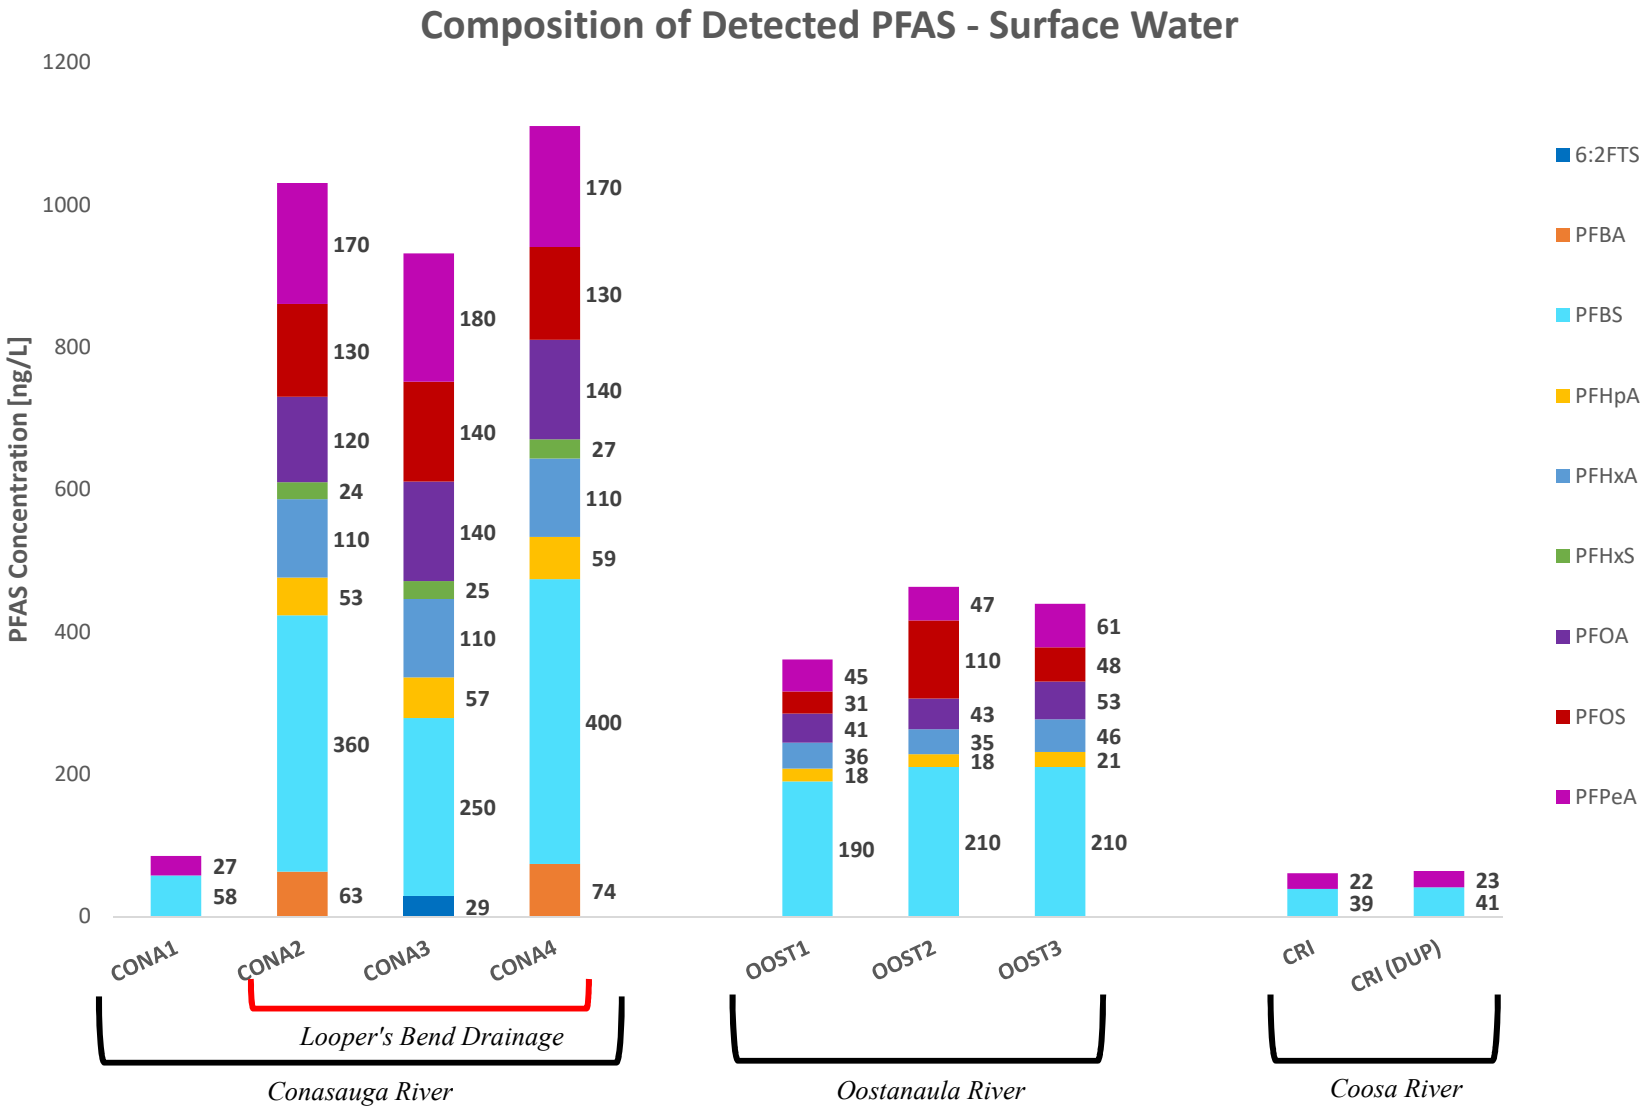
Upper Coosa River Basin

0 1.5 3 6 9 12

Miles

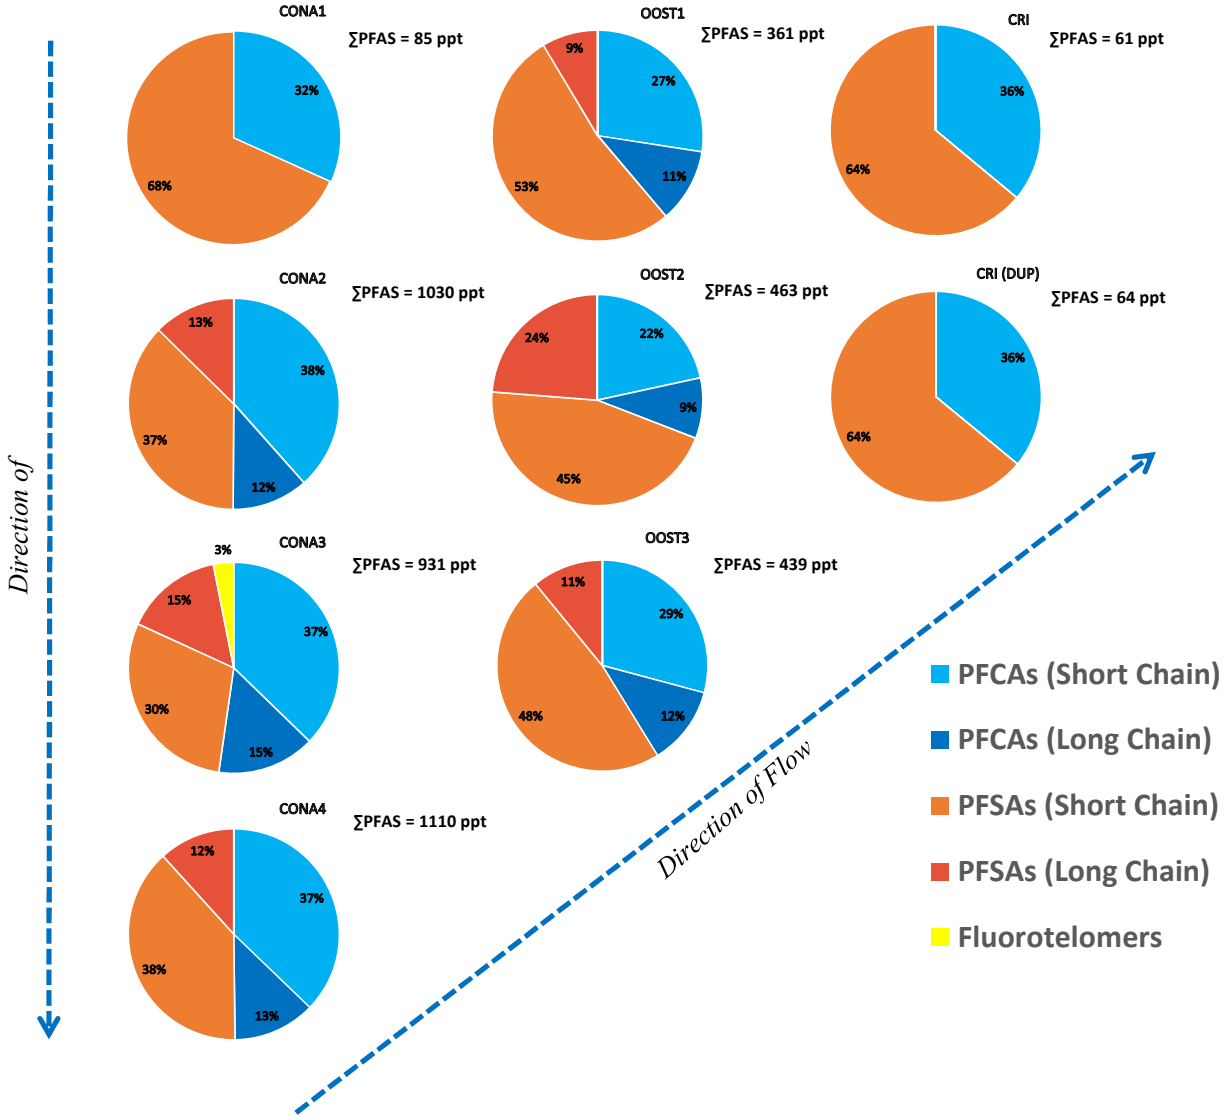
- USGS Gages
- Sampling Stations
- Rivers
- Looper's Bend LAS Boundary

Figure 2: Composition of PFAS Detected in Surface Water



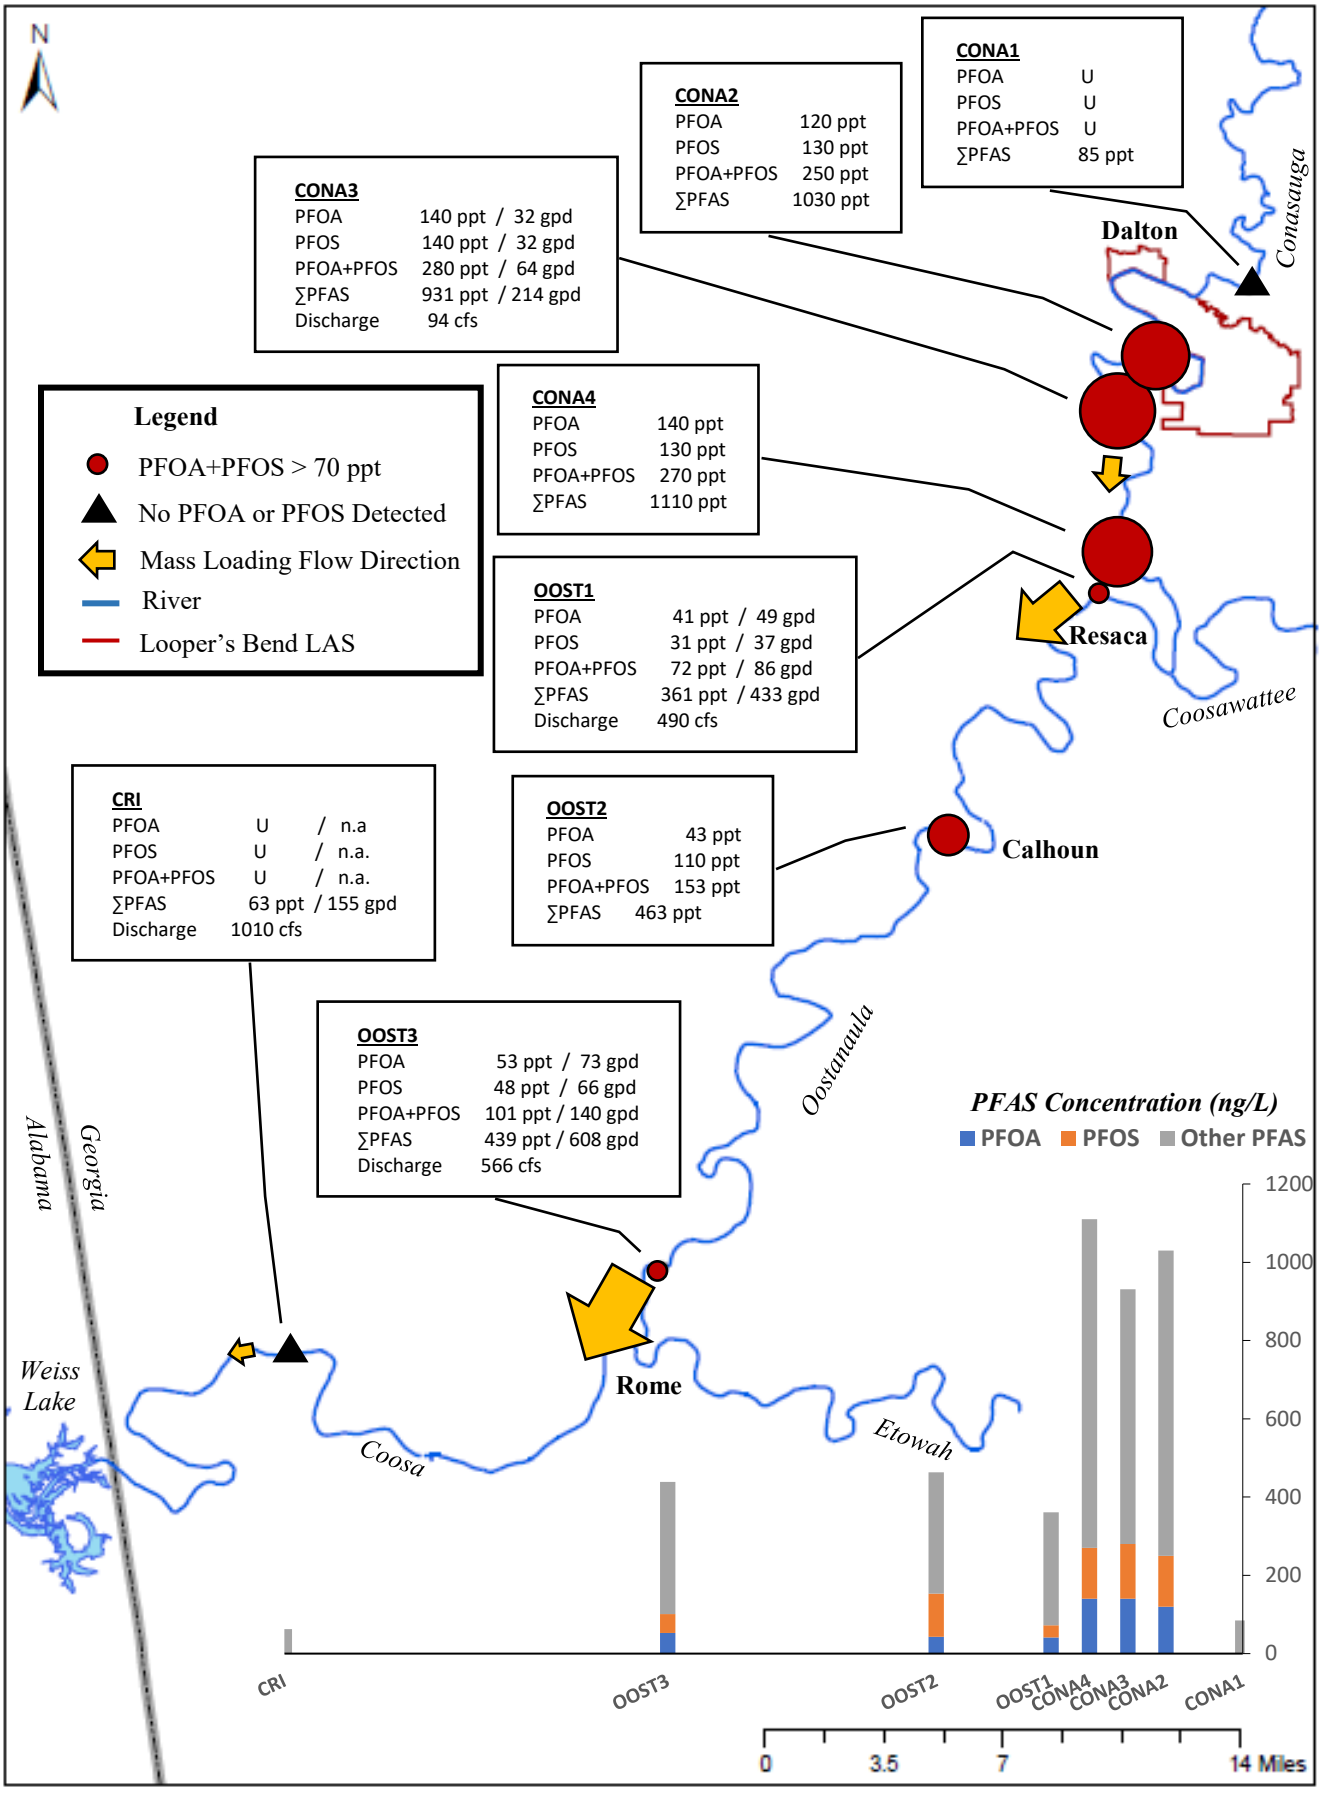
Samples collected on the Conasauga River downstream of Looper's Bend LAS had the highest diversity of PFAS followed by samples collected on the Oostanaula River.

Figure 3: PFAS Class and Functional Groups Detected in Surface Water



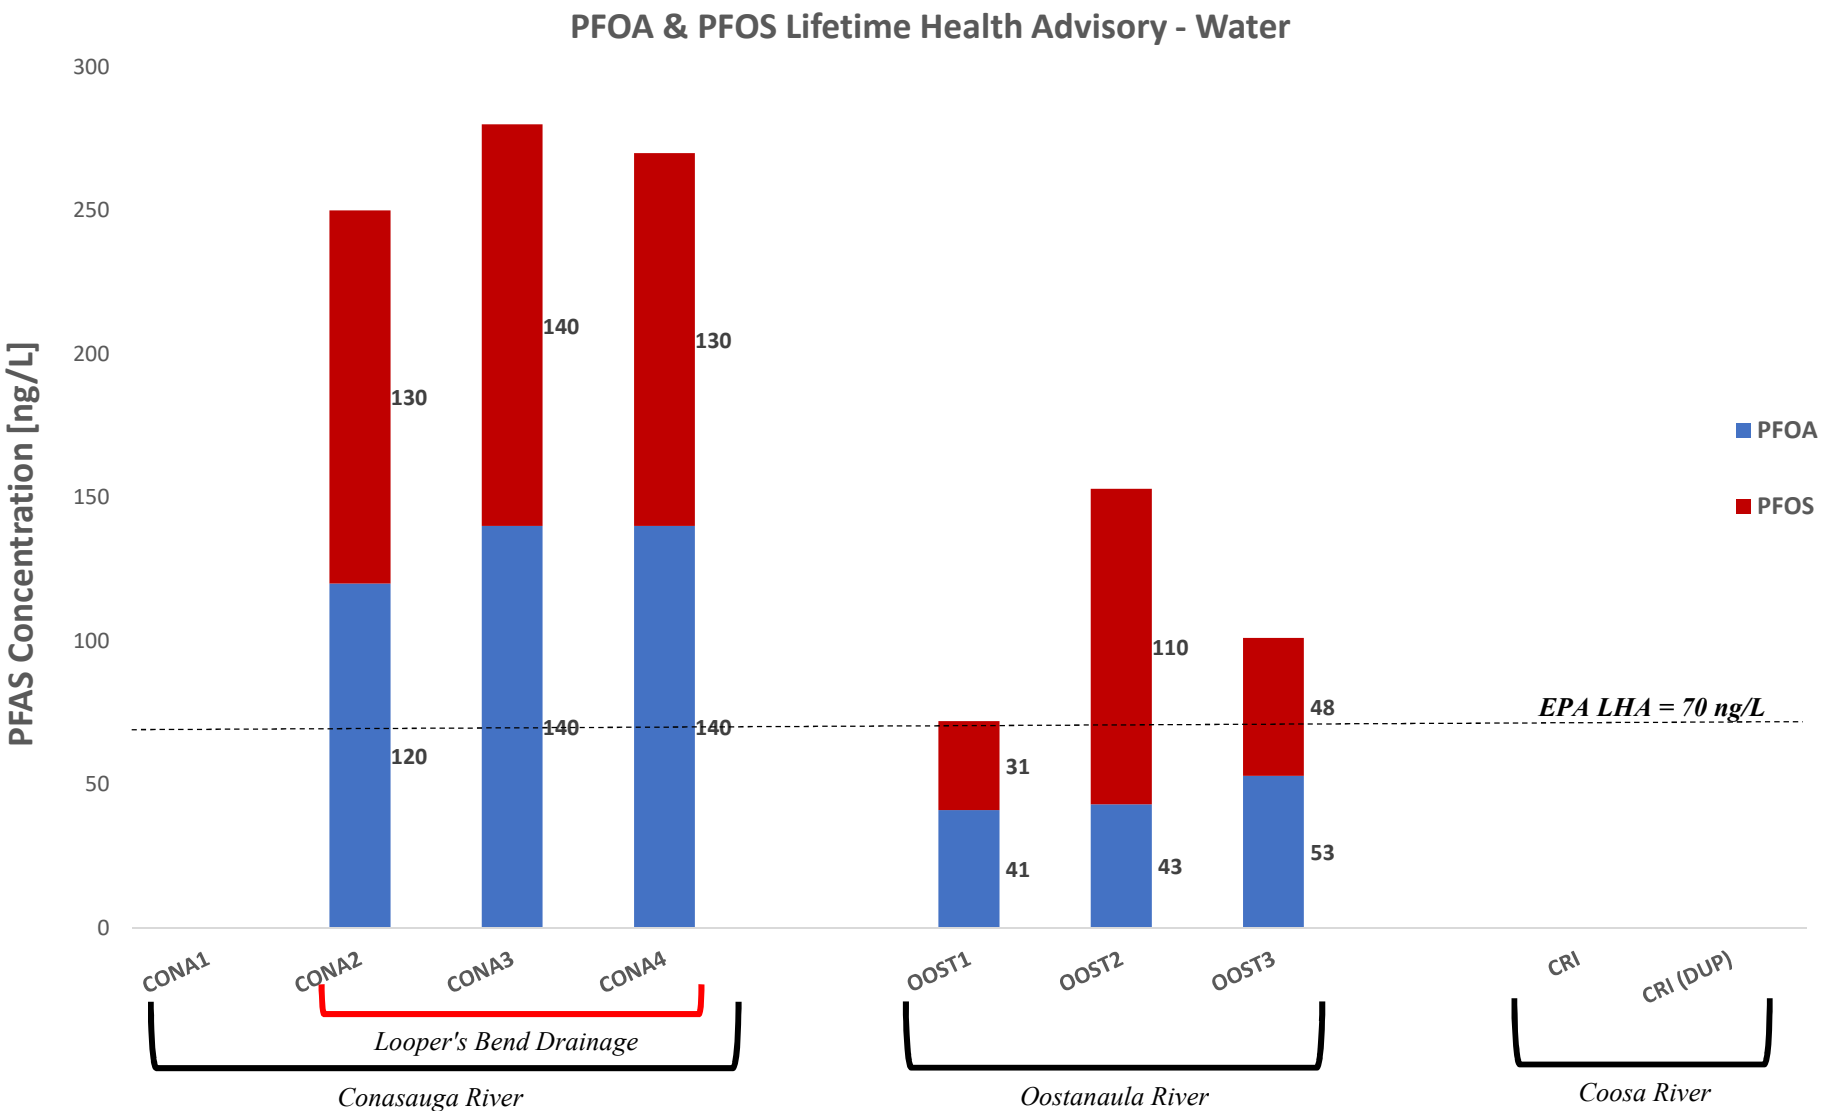
Surface water samples were predominately composed of short-chain PFAS with a moderate presence of long-chain compounds found in the Conasauga and Oostanaula Rivers, downstream of Looper's Bend LAS. The fluorotelomer 6:2 FTS was also detected at CONA3 which is known to be a precursor to short-chain PFCAs.

Figure 4: Distribution and Mass Loading of PFAS in Surface Water



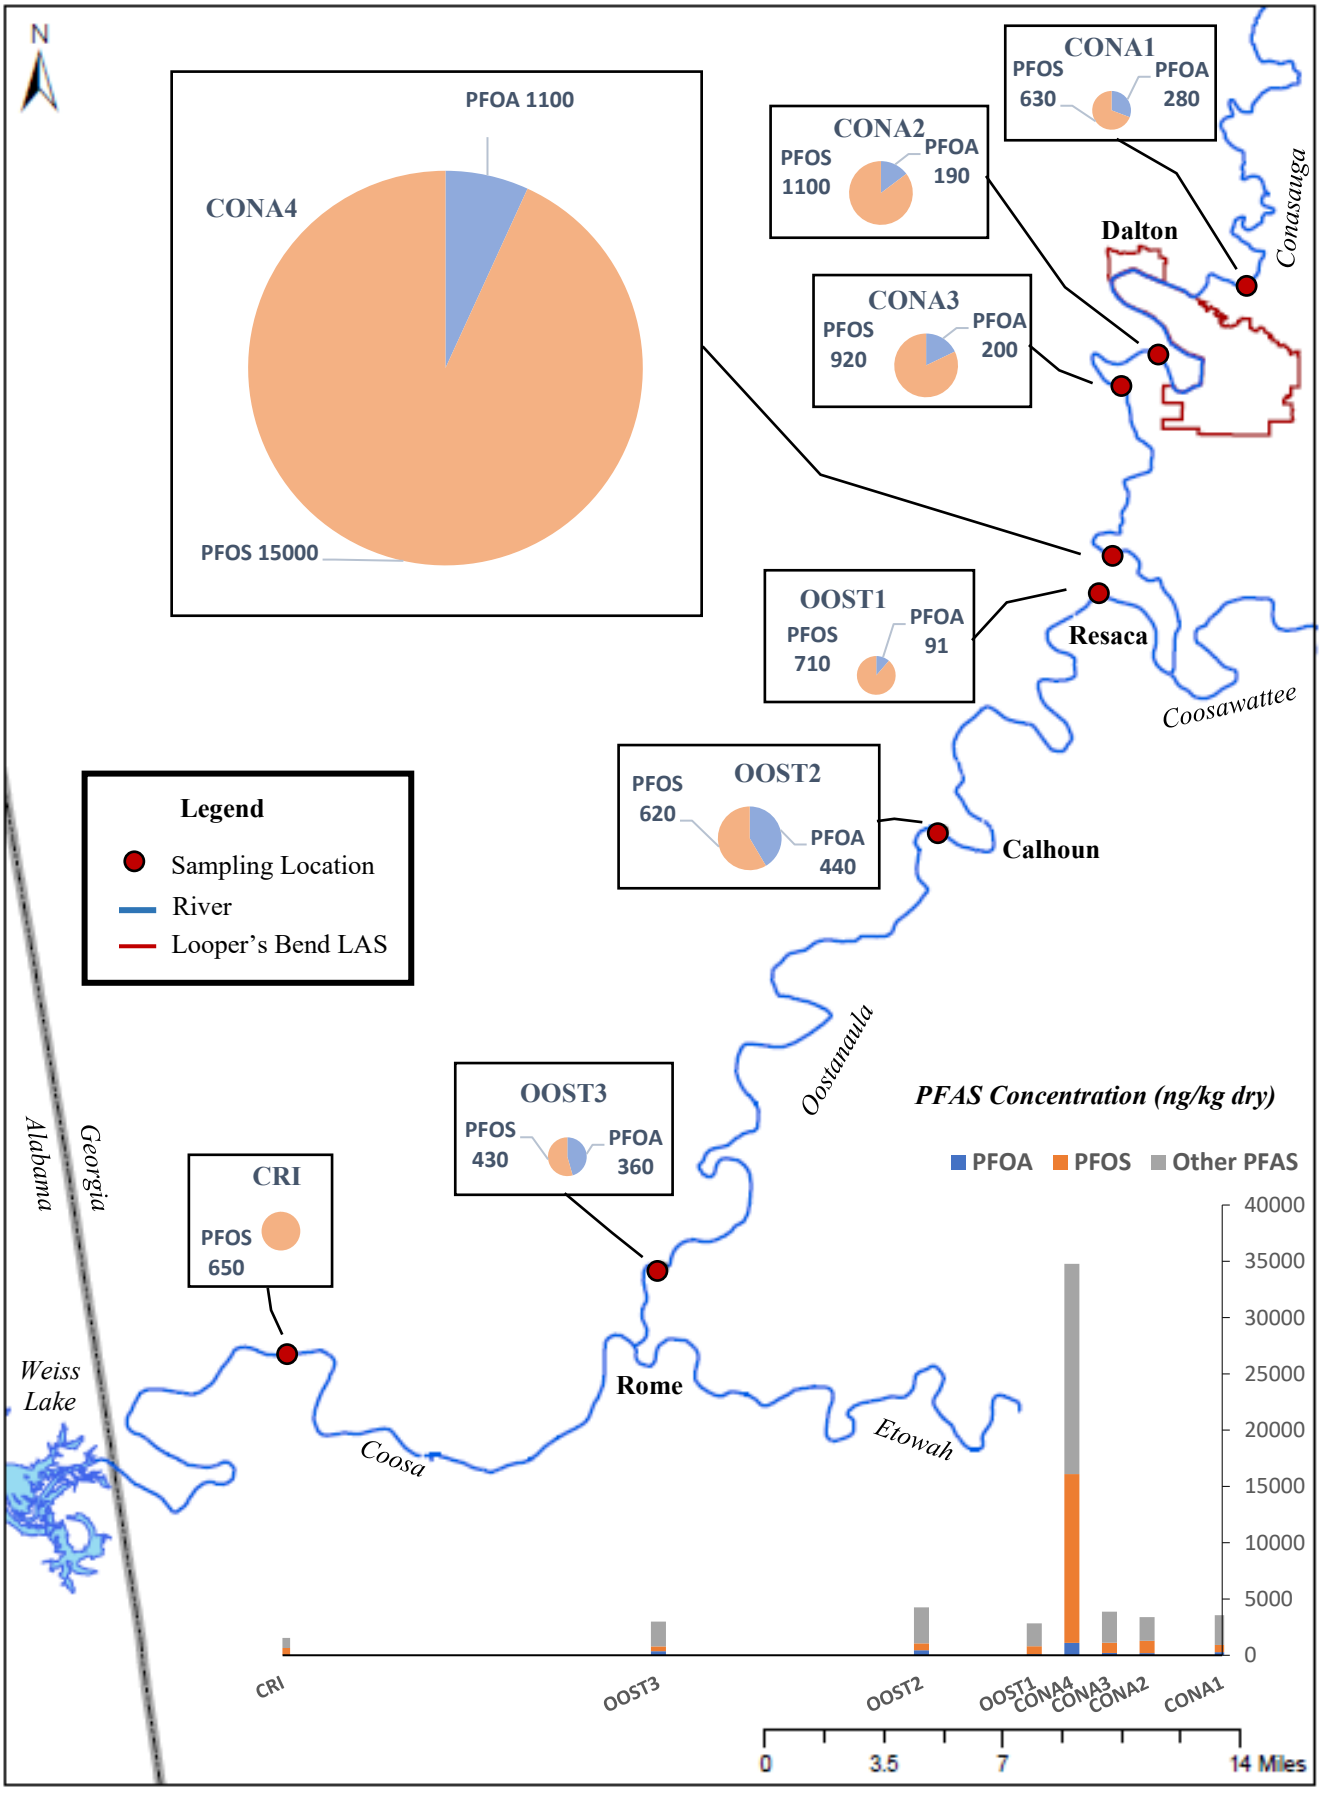
PFAS concentrations are in ng/L (ppt) and mass loading rates are in grams per day (gpd). Flow directional arrows and sampling locations are shown in relative proportion based on total PFAS loading and PFOA+PFOS, respectively.

Figure 5: PFOA and PFOS in Surface Water



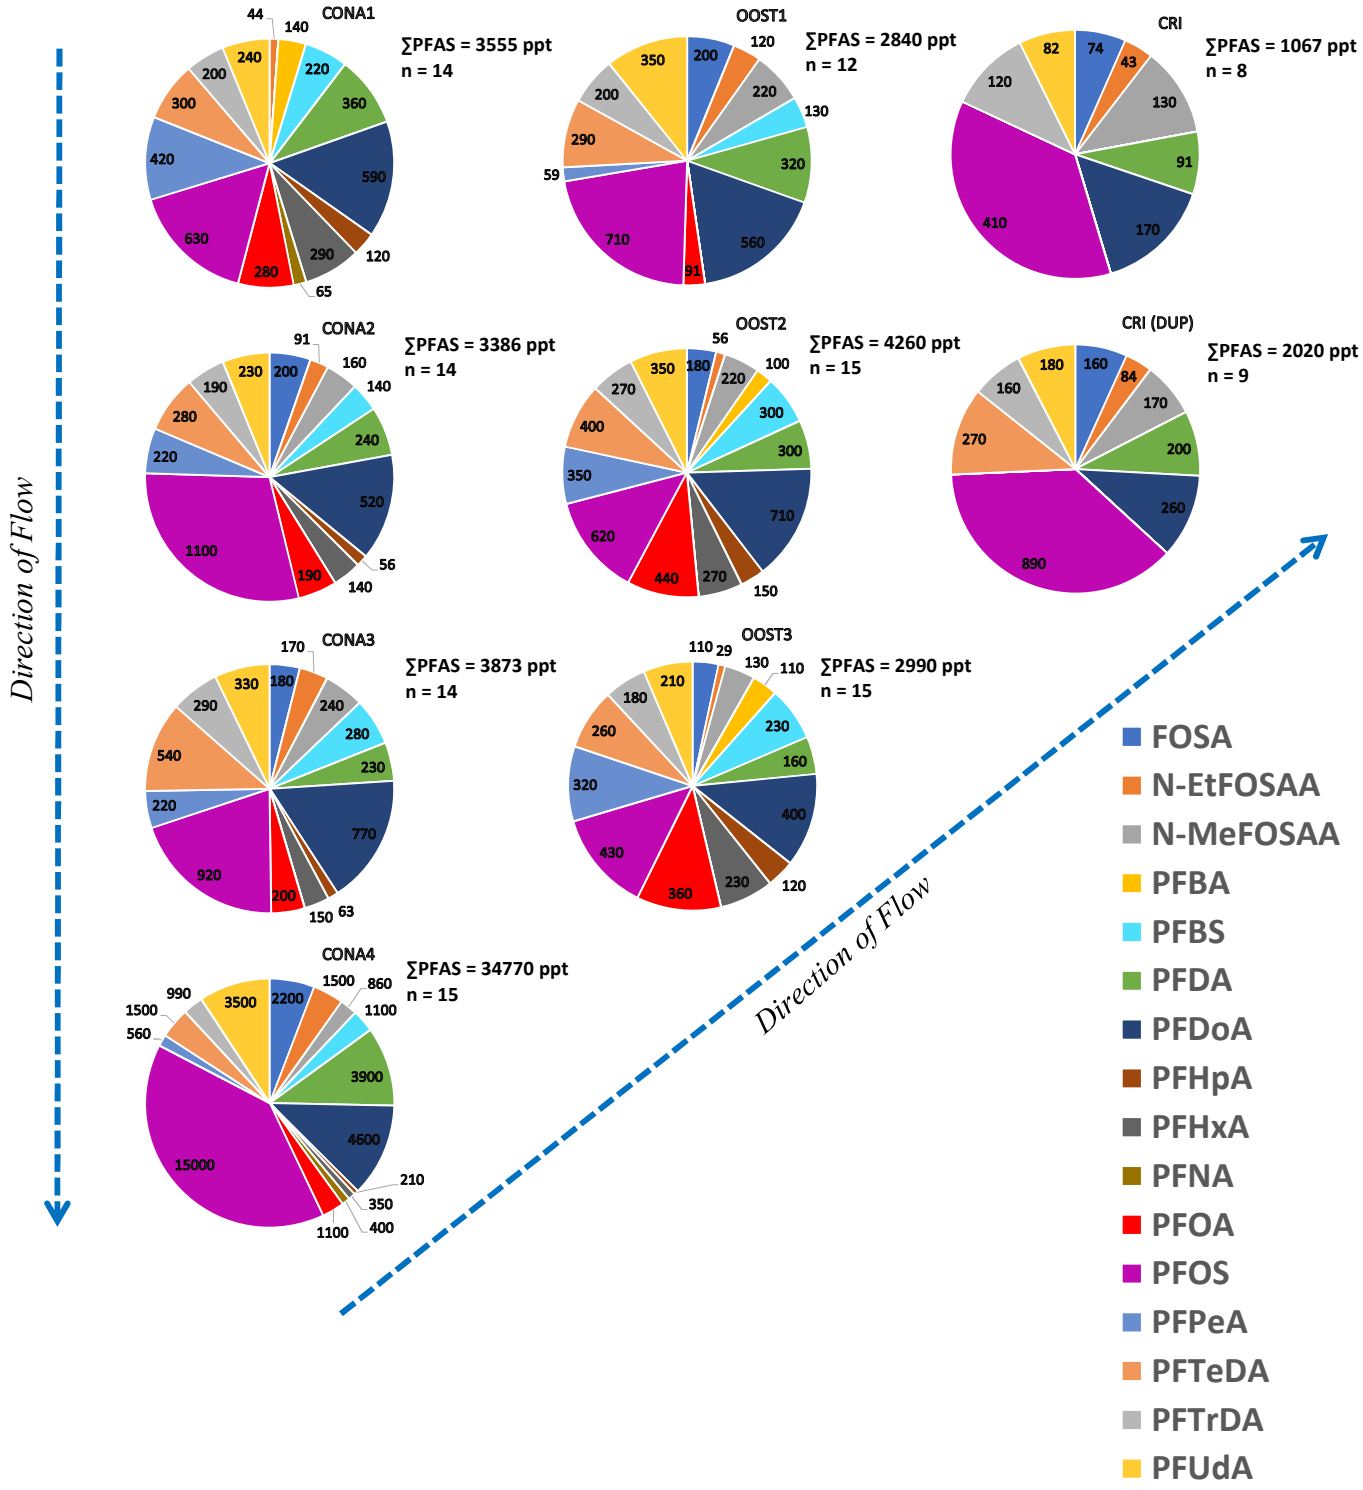
Combined PFOA and PFOS concentrations were approximately 3 times greater than the EPA's lifetime health advisory (LHA) of 70 ppt on the Conasauga River downstream of Looper's Bend LAS with residual concentrations detected at or above the LHA on the Oostanaula River.

Figure 6: Distribution of PFAS in Sediments



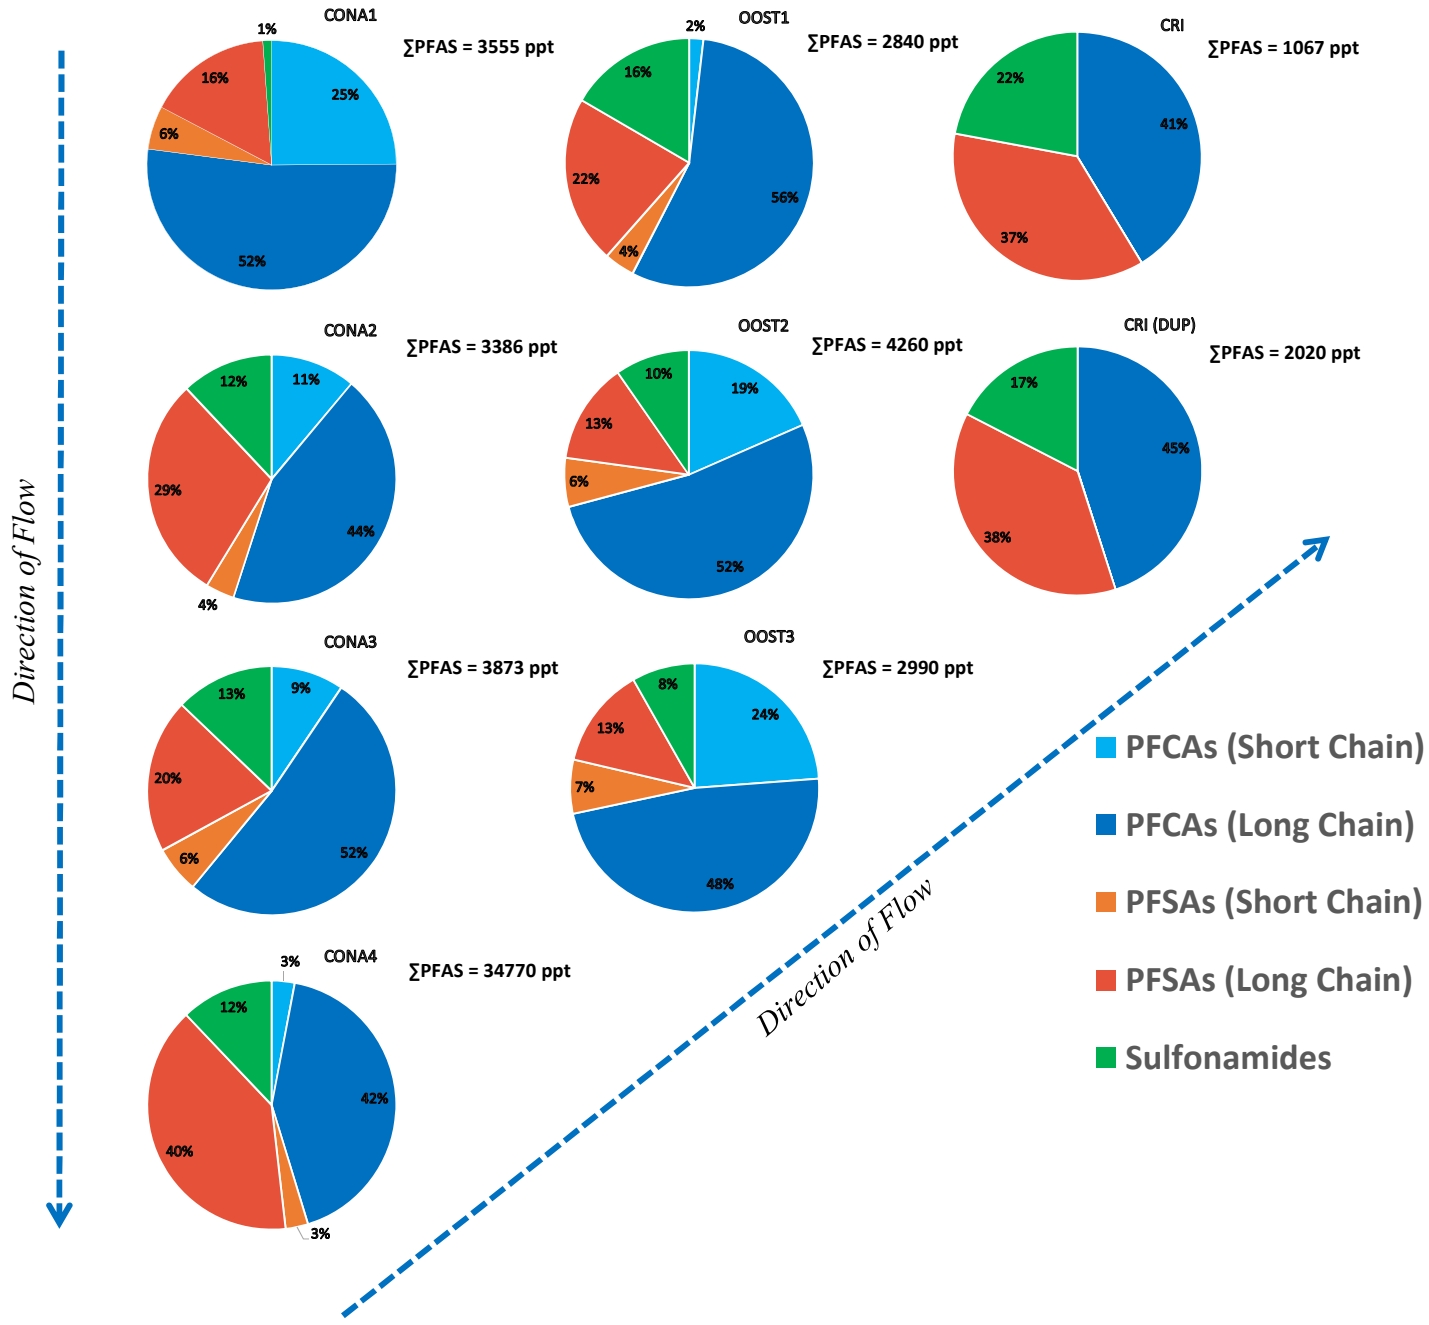
All PFAS concentrations are in ng/kg *dry* (ppt). Pie charts are shown in relative proportions based on combined PFOA and PFOS.

Figure 7: Composition of Detected PFAS in Sediments



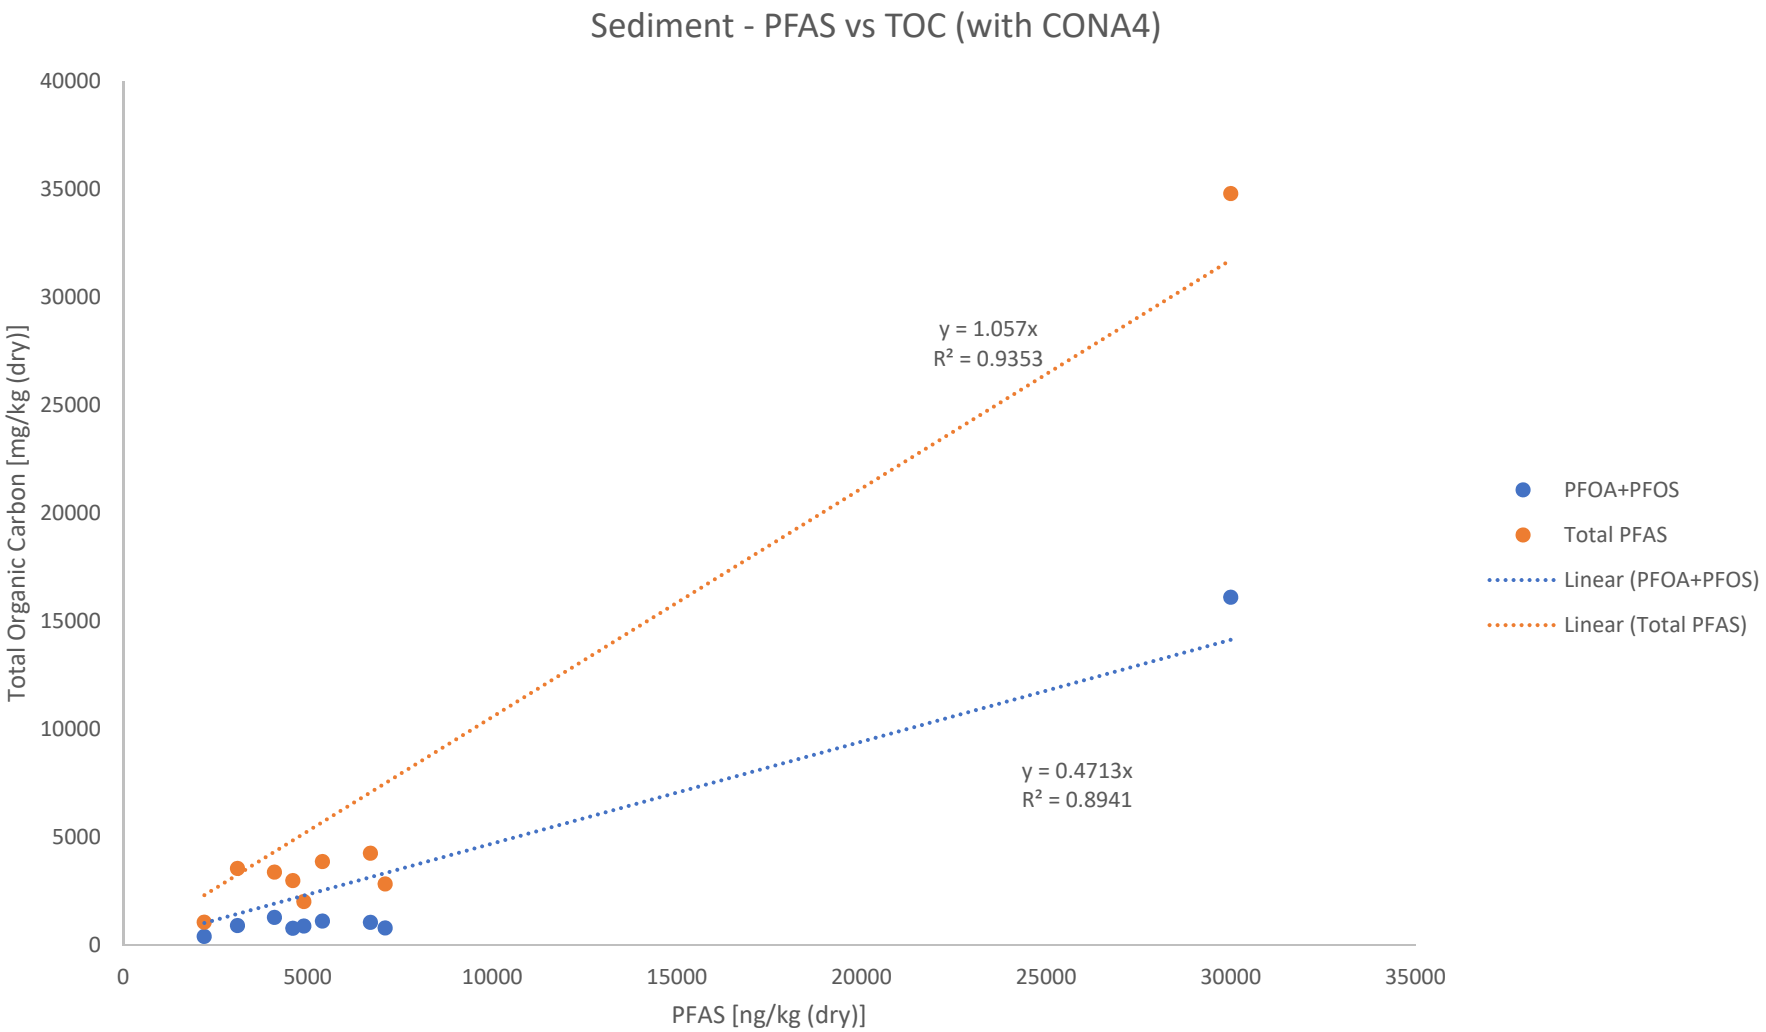
Concentrations of PFAS detected in sediment samples are shown on pie charts in units of ng/kg *dry* (ppt). All sediment samples were relatively diverse in the composition of detected PFAS compounds throughout the watershed.

Figure 8: PFAS Class and Functional Groups Detected in Sediment



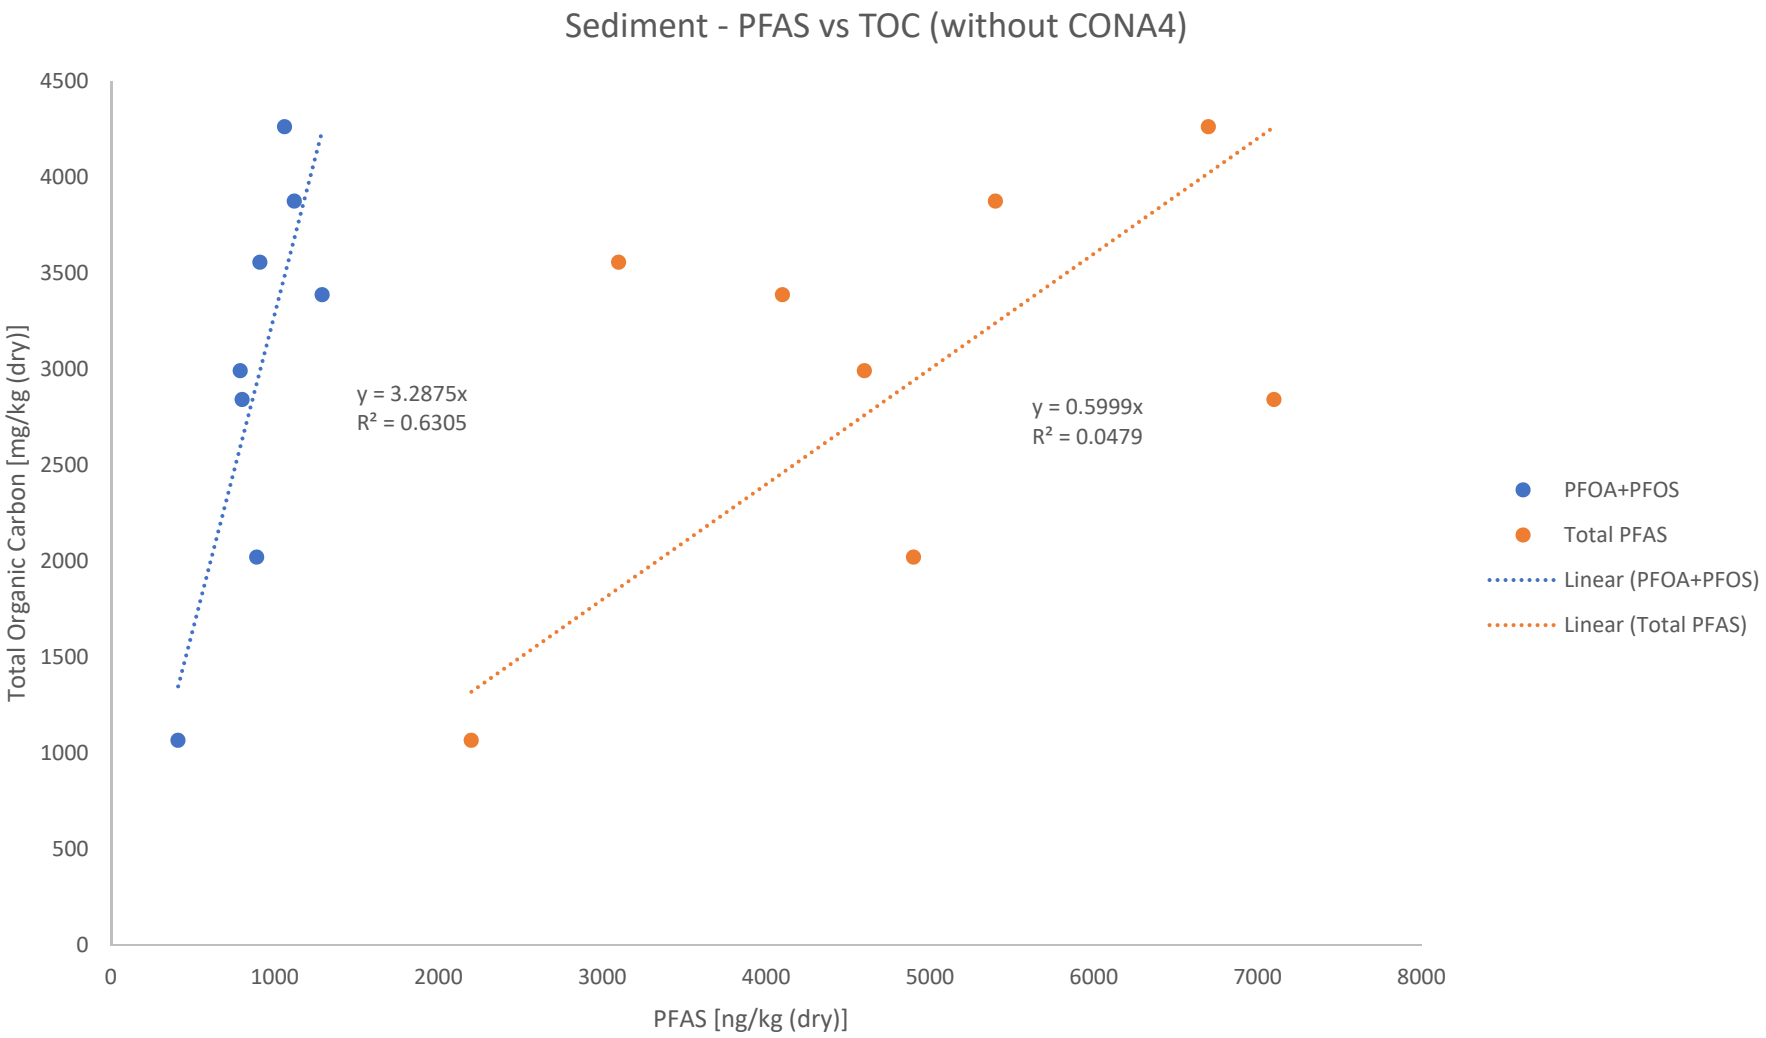
Sediments were predominately composed of long-chain PFAS. Sulfonamides were detected throughout the watershed which are known to be precursors to both PFOS and PFOA.

Figure 9: Sediment TOC and PFAS Retention (CONA4 Included)



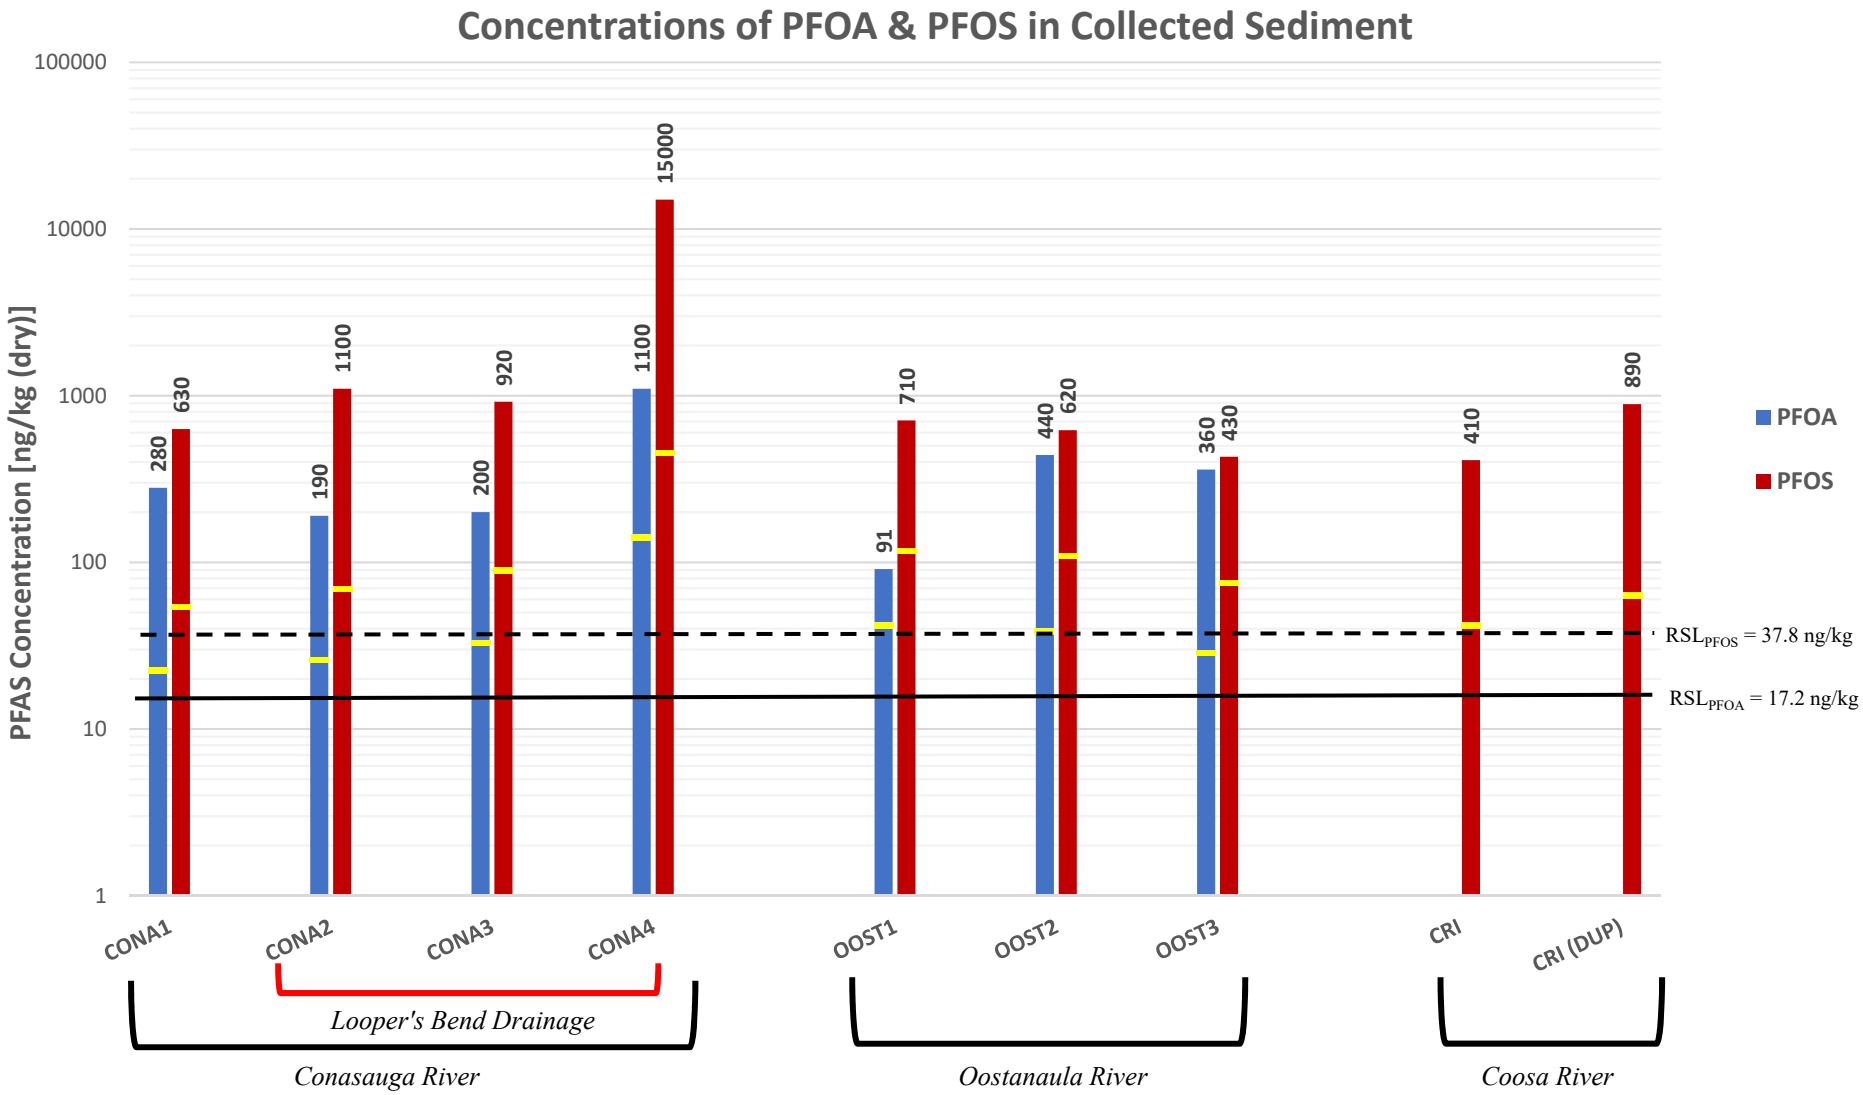
Concentrations of PFAS detected in sediments collected at CONA4 on the Conasauga River were found to be orders of magnitude above conentrations observed at all other sites. This was found to be mainly driven by the presence of total organic carbon at similiarly high concentrations in the sediment sample collected at CONA4.

Figure 10: Sediment TOC and PFAS Retention (CONA4 Excluded)



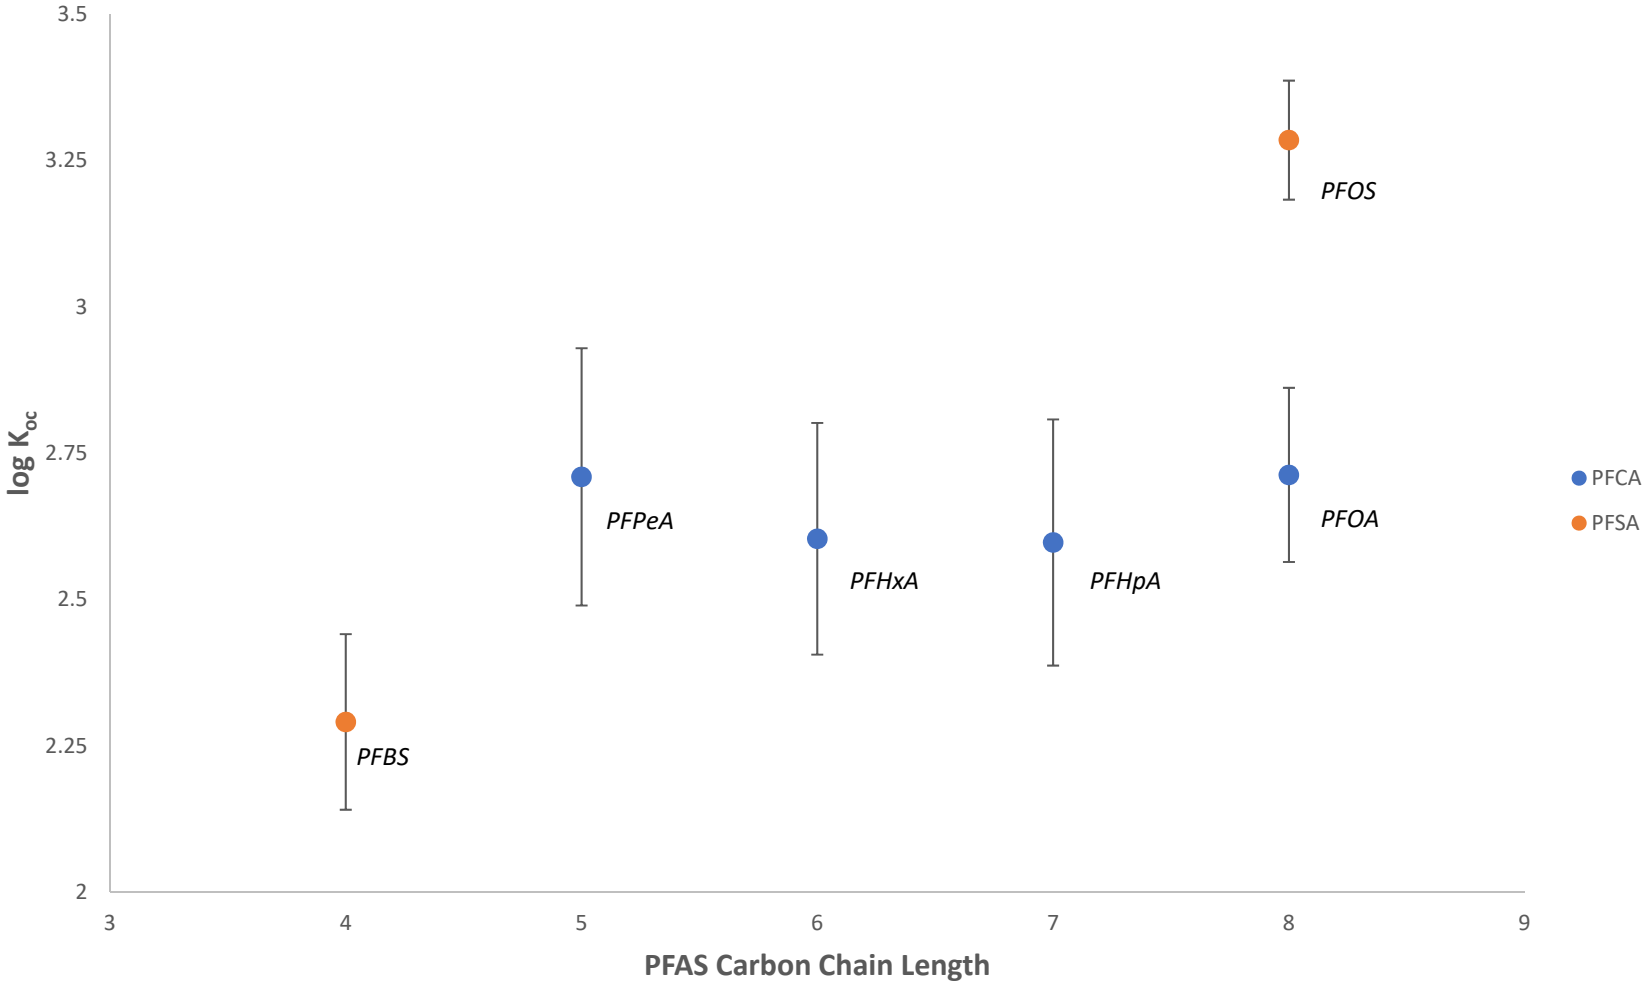
With CONA4 removed as an outlier, combined concentrations of PFOA and PFOS detected in the sediments are still generally influenced by the presence of total organic carbon. The relationship between Total PFAS concentrations and total organic carbon is inconclusive due to differing effects of oragnic carbon on the retention of PFAS compounds depending on the carbon chain length and functional group as seen in Figure 12.

Figure 11: PFOA and PFOS Detected in Sediments



PFOA and PFOS were detected at concentrations above both generic and site-specific risk screening levels (RSLs) corrected for total organic carbon throughout the watershed. PFOA was not detected at or above the MRL on the Coosa River. Generic RSLs are represented by the solid and dashed lines for PFOA and PFOS, respectively. Yellow lines depict the site-specific RSLs corrected for the organic carbon fraction at each site.

Figure 12: Organic Carbon Partition Coefficients (K_{oc}) of Detected PFAS



The effect of organic carbon and the retention of PFAS in sediments is dependent on both the chain length and functional group. PFAS retention in sediments generally increases with increasing chain length and PFSAs (*e.g.* PFOS) are more likely to be retained compared to PFCAs (*e.g.* PFOA) of the same chain length.

MEMORANDUM

SUBJECT: FINAL Analytical Report
Project: 19-0457, PFAS Sediment Screening - Conasauga R

FROM: Diana Burdette
OCS Analyst

THRU: Jeffrey Hendel, Chief
LSB Organic Chemistry Section

TO: Nathan Barlet

Attached are the final results for the analytical groups listed below. This report shall not be reproduced except in full without approval of the Region 4 laboratory. These analyses were performed in accordance with the Laboratory Services Branch's Laboratory Operations and Quality Assurance Manual (LSB LOQAM) found at www.epa.gov/region4/sesd/asbsop. Any unique project data quality objectives specified in writing by the data requestor have also been incorporated into the data unless otherwise noted in the Report Narrative. Chemistry data have been verified based on the LSB LOQAM specifications and have been qualified by this laboratory if the applicable quality control criteria were not met. Verification is defined in Chapter 5 of the LSB LOQAM. For a listing of specific data qualifiers and explanations, please refer to the Data Qualifier Definitions included in this report. The reported results are accurate within the limits of the method(s) and are representative only of the samples as received by the laboratory.

Analyses Included in this report:	Method Used:	Accreditations:
Semi Volatile Organics (SVOA)		
PFAS	ASBPROC-800PFAS (Water)

Sample Disposal Policy

Due to limited space for long term sample storage, LSB's policy is to dispose of samples on a periodic schedule. Air samples collected in summa canisters will be disposed of 30 days following the issuance of this report. All other sample media including original samples, sample extracts and or digestates will be disposed of, in accordance with applicable regulations, 60 days from the date of this report.

This sample disposal policy does not apply to criminal samples which are held until the laboratory is notified by the criminal investigators that case development and litigation are complete.

These samples may be held in the laboratory's custody for a longer period of time. If samples require storage beyond the 60-day period, please contact the Sample Control Coordinator by e-mail at R4SampleCustody@epa.gov.

D.A.R.T. Id: 19-0457
Project: 19-0457, PFAS Sediment Screening - Conasauga R - Reported by Diana Burdette

DATA QUALIFIER DEFINITIONS

U	The analyte was not detected at or above the reporting limit.
CR	Less than MDL and MRL, Data system set to display the concentration of a known spiked sample
CRa	Less than MDL and MRL, Data system set to display the concentration of a known spiked sample.
J	The identification of the analyte is acceptable; the reported value is an estimate.
Q-2	Result greater than MDL but less than MRL.
QS-3	Surrogate recovery is lower than established control limits.
QS-5	Surrogate recovery is higher than established control limits
Y-2	Data should be limited to screening purposes only

ACRONYMS AND ABBREVIATIONS

CAS Chemical Abstracts Service

Note: Analytes with no known CAS identifiers have been assigned codes beginning with "E", the EPA ID as assigned by the EPA Substance Registry System (www.epa.gov/srs), or beginning with "R4-", a unique identifier assigned by the EPA Region 4 laboratory.

MDL Method Detection Limit - The minimum concentration of a substance (an analyte) that can be measured and reported with a 99% confidence that the analyte concentration is greater than zero.

MRL Minimum Reporting Limit - Analyte concentration that corresponds to the lowest demonstrated level of acceptable quantitation. The MRL is sample-specific and accounts for preparation weights and volumes, dilutions, and moisture content of soil/sediments.

TIC Tentatively Identified Compound - An analyte identified based on a match with the instrument software's mass spectral library. A calibration standard has not been analyzed to confirm the compound's identification or the estimated concentration reported.

ACCREDITATIONS:

ISO ASB is accredited by ISO/IEC 17025, including an amplification for forensic accreditation through ANSI-ASQ National Accreditation Board.

Refer to the certificate and scope of accreditation AT-1644 at:
http://www.epa.gov/aboutepa/about-region-4s-science-and-ecosystem-support-division-sesd

NR The EPA Region 4 Laboratory has not requested accreditation for this test.

Notes and Definitions for QC Samples

U	The analyte was not detected at or above the reporting limit.
J	The identification of the analyte is acceptable; the reported value is an estimate.
MRL-2	MRL verification for Non-Potable Water matrix
Q-2	Result greater than MDL but less than MRL.
Y-2	Data should be limited to screening purposes only

MEMORANDUM

SUBJECT: FINAL Analytical Report
Project: 19-0457, PFAS Sediment Screening - Conasauga R

FROM: Jeffrey Hendel
LSB Organic Chemistry Section Chief

THRU: Sandra Aker, Chief
Laboratory Services Branch

TO: Nathan Barlet

Attached are the final results for the analytical groups listed below. This report shall not be reproduced except in full without approval of the Region 4 laboratory. These analyses were performed in accordance with the Laboratory Services Branch's Laboratory Operations and Quality Assurance Manual (LSB LOQAM) found at www.epa.gov/region4/sesd/asbsop. Any unique project data quality objectives specified in writing by the data requestor have also been incorporated into the data unless otherwise noted in the Report Narrative. Chemistry data have been verified based on the LSB LOQAM specifications and have been qualified by this laboratory if the applicable quality control criteria were not met. Verification is defined in Chapter 5 of the LSB LOQAM. For a listing of specific data qualifiers and explanations, please refer to the Data Qualifier Definitions included in this report. The reported results are accurate within the limits of the method(s) and are representative only of the samples as received by the laboratory.

Analyses Included in this report:	Method Used:	Accreditations:
Semi Volatile Organics (SVOA)		
PFAS	ASBPROC-800PFAS (Water)

---

Sample Disposal Policy

Due to limited space for long term sample storage, LSB's policy is to dispose of samples on a periodic schedule. Air samples collected in summa canisters will be disposed of 30 days following the issuance of this report. All other sample media including original samples, sample extracts and or digestates will be disposed of, in accordance with applicable regulations, 60 days from the date of this report.

This sample disposal policy does not apply to criminal samples which are held until the laboratory is notified by the criminal investigators that case development and litigation are complete.

These samples may be held in the laboratory's custody for a longer period of time. If samples require storage beyond the 60-day period, please contact the Sample Control Coordinator by e-mail at R4SampleCustody@epa.gov.

DATA QUALIFIER DEFINITIONS

U	The analyte was not detected at or above the reporting limit.
J	The identification of the analyte is acceptable; the reported value is an estimate.
QC-1	Analyte concentration low in continuing calibration verification standard
QC-3	Analyte calibration criteria not met
QC-5	Calibration check standard less than method control limits.
Y-2	Data should be limited to screening purposes only

ACRONYMS AND ABBREVIATIONS

CAS Chemical Abstracts Service

Note: Analytes with no known CAS identifiers have been assigned codes beginning with "E", the EPA ID as assigned by the EPA Substance Registry System (www.epa.gov/srs), or beginning with "R4-", a unique identifier assigned by the EPA Region 4 laboratory.

MDL Method Detection Limit - The minimum concentration of a substance (an analyte) that can be measured and reported with a 99% confidence that the analyte concentration is greater than zero.

MRL Minimum Reporting Limit - Analyte concentration that corresponds to the lowest demonstrated level of acceptable quantitation. The MRL is sample-specific and accounts for preparation weights and volumes, dilutions, and moisture content of soil/sediments.

TIC Tentatively Identified Compound - An analyte identified based on a match with the instrument software's mass spectral library. A calibration standard has not been analyzed to confirm the compound's identification or the estimated concentration reported.

ACCREDITATIONS:

ISO ASB is accredited by ISO/IEC 17025, including an amplification for forensic accreditation through ANSI-ASQ National Accreditation Board.

Refer to the certificate and scope of accreditation AT-1644 at:
http://www.epa.gov/aboutepa/about-region-4s-science-and-ecosystem-support-division-sesd

NR The EPA Region 4 Laboratory has not requested accreditation for this test.

Notes and Definitions for QC Samples

U	The analyte was not detected at or above the reporting limit.
J	The identification of the analyte is acceptable; the reported value is an estimate.
MRL-2	MRL verification for Non-Potable Water matrix
Q-2	Result greater than MDL but less than MRL.
QC-1	Analyte concentration low in continuing calibration verification standard
QC-3	Analyte calibration criteria not met
QL-2	Laboratory Control Spike Recovery greater than method control limits
Y-2	Data should be limited to screening purposes only

MEMORANDUM

SUBJECT: FINAL Analytical Report
Project: 19-0457, PFAS Sediment Screening - Conasauga R

FROM: Diana Burdette
OCS Analyst

THRU: Jeffrey Hendel, Chief
LSB Organic Chemistry Section

TO: Nathan Barlet

Attached are the final results for the analytical groups listed below. This report shall not be reproduced except in full without approval of the Region 4 laboratory. These analyses were performed in accordance with the Laboratory Services Branch's Laboratory Operations and Quality Assurance Manual (LSB LOQAM) found at www.epa.gov/region4/sesd/asbsop. Any unique project data quality objectives specified in writing by the data requestor have also been incorporated into the data unless otherwise noted in the Report Narrative. Chemistry data have been verified based on the LSB LOQAM specifications and have been qualified by this laboratory if the applicable quality control criteria were not met. Verification is defined in Chapter 5 of the LSB LOQAM. For a listing of specific data qualifiers and explanations, please refer to the Data Qualifier Definitions included in this report. The reported results are accurate within the limits of the method(s) and are representative only of the samples as received by the laboratory.

Analyses Included in this report:	Method Used:	Accreditations:
Semi Volatile Organics (SVOA)		
PFAS	ASBPROC-800PFAS (Soil)

Sample Disposal Policy

Due to limited space for long term sample storage, LSB's policy is to dispose of samples on a periodic schedule. Air samples collected in summa canisters will be disposed of 30 days following the issuance of this report. All other sample media including original samples, sample extracts and or digestates will be disposed of, in accordance with applicable regulations, 60 days from the date of this report.

This sample disposal policy does not apply to criminal samples which are held until the laboratory is notified by the criminal investigators that case development and litigation are complete.

These samples may be held in the laboratory's custody for a longer period of time. If samples require storage beyond the 60-day period, please contact the Sample Control Coordinator by e-mail at R4SampleCustody@epa.gov.

DATA QUALIFIER DEFINITIONS

U	The analyte was not detected at or above the reporting limit.
J	The identification of the analyte is acceptable; the reported value is an estimate.
Q-2	Result greater than MDL but less than MRL.
QC-3	Analyte calibration criteria not met
QR-2	MRL verification recovery greater than upper control limits.
QS-5	Surrogate recovery is higher than established control limits
Y-2	Data should be limited to screening purposes only

ACRONYMS AND ABBREVIATIONS

CAS Chemical Abstracts Service

Note: Analytes with no known CAS identifiers have been assigned codes beginning with "E", the EPA ID as assigned by the EPA Substance Registry System (www.epa.gov/srs), or beginning with "R4-", a unique identifier assigned by the EPA Region 4 laboratory.

MDL Method Detection Limit - The minimum concentration of a substance (an analyte) that can be measured and reported with a 99% confidence that the analyte concentration is greater than zero.

MRL Minimum Reporting Limit - Analyte concentration that corresponds to the lowest demonstrated level of acceptable quantitation. The MRL is sample-specific and accounts for preparation weights and volumes, dilutions, and moisture content of soil/sediments.

TIC Tentatively Identified Compound - An analyte identified based on a match with the instrument software's mass spectral library. A calibration standard has not been analyzed to confirm the compound's identification or the estimated concentration reported.

ACCREDITATIONS:

ISO ASB is accredited by ISO/IEC 17025, including an amplification for forensic accreditation through ANSI-ASQ National Accreditation Board.

Refer to the certificate and scope of accreditation AT-1644 at:
http://www.epa.gov/aboutepa/about-region-4s-science-and-ecosystem-support-division-sesd

NR The EPA Region 4 Laboratory has not requested accreditation for this test.

Notes and Definitions for QC Samples

U	The analyte was not detected at or above the reporting limit.
J	The identification of the analyte is acceptable; the reported value is an estimate.
MRL-3	MRL verification for Soil matrix
Q-2	Result greater than MDL but less than MRL.
QC-3	Analyte calibration criteria not met
QR-2	MRL verification recovery greater than upper control limits.
Y-2	Data should be limited to screening purposes only

MEMORANDUM

SUBJECT: FINAL Analytical Report
Project: 19-0457, PFAS Sediment Screening - Conasauga R

FROM: Floyd Wellborn
LSB Inorganic Chemistry Section Chief

THRU: Sandra Aker, Chief
Laboratory Services Branch

TO: Nathan Barlet

Attached are the final results for the analytical groups listed below. This report shall not be reproduced except in full without approval of the Region 4 laboratory. These analyses were performed in accordance with the Laboratory Services Branch's Laboratory Operations and Quality Assurance Manual (LSB LOQAM) found at www.epa.gov/region4/sesd/asbsop. Any unique project data quality objectives specified in writing by the data requestor have also been incorporated into the data unless otherwise noted in the Report Narrative. Chemistry data have been verified based on the LSB LOQAM specifications and have been qualified by this laboratory if the applicable quality control criteria were not met. Verification is defined in Chapter 5 of the LSB LOQAM. For a listing of specific data qualifiers and explanations, please refer to the Data Qualifier Definitions included in this report. The reported results are accurate within the limits of the method(s) and are representative only of the samples as received by the laboratory.

Analyses Included in this report:	Method Used:	Accreditations:
Classical/Nutrient Analyses (CNA)		
Classical/Nutrients	ASB 107C (Soil)	ISO
Classical/Nutrients	SM 5310B (Water)	ISO
Solids	USGS I-3765-85 (Water)	ISO
Physical Properties (PHYSP)		
Physical Properties	EPA 200.2 (Soil)	ISO

Report Narrative for Work Order: E193805 Analysis: CNA

10/21/19 FW: These results are re-reported at the request of the project leader to include estimated results for TOC in soil down to the MDL. No other results were changed. This report replaces E193805 CNA PHYSP FINAL 10 10 19 1452.

Sample Disposal Policy

Due to limited space for long term sample storage, LSB's policy is to dispose of samples on a periodic schedule. Air samples collected in summa canisters will be disposed of 30 days following the issuance of this report. All other sample media including original samples, sample extracts and or digestates will be disposed of, in accordance with applicable regulations, 60 days from the date of this report.

This sample disposal policy does not apply to criminal samples which are held until the laboratory is notified by the criminal investigators that case development and litigation are complete.

These samples may be held in the laboratory's custody for a longer period of time. If samples require storage beyond the 60-day period, please contact the Sample Control Coordinator by e-mail at R4SampleCustody@epa.gov.

DATA QUALIFIER DEFINITIONS

J The identification of the analyte is acceptable; the reported value is an estimate.

Q-2 Result greater than MDL but less than MRL.

ACRONYMS AND ABBREVIATIONS

CAS Chemical Abstracts Service

Note: Analytes with no known CAS identifiers have been assigned codes beginning with "E", the EPA ID as assigned by the EPA Substance Registry System (www.epa.gov/srs), or beginning with "R4-", a unique identifier assigned by the EPA Region 4 laboratory.

MDL Method Detection Limit - The minimum concentration of a substance (an analyte) that can be measured and reported with a 99% confidence that the analyte concentration is greater than zero.

MRL Minimum Reporting Limit - Analyte concentration that corresponds to the lowest demonstrated level of acceptable quantitation. The MRL is sample-specific and accounts for preparation weights and volumes, dilutions, and moisture content of soil/sediments.

TIC Tentatively Identified Compound - An analyte identified based on a match with the instrument software's mass spectral library. A calibration standard has not been analyzed to confirm the compound's identification or the estimated concentration reported.

ACCREDITATIONS:

ISO ASB is accredited by ISO/IEC 17025, including an amplification for forensic accreditation through ANSI-ASQ National Accreditation Board.

Refer to the certificate and scope of accreditation AT-1644 at:
http://www.epa.gov/aboutepa/about-region-4s-science-and-ecosystem-support-division-sesd

NR The EPA Region 4 Laboratory has not requested accreditation for this test.

Notes and Definitions for QC Samples

U	The analyte was not detected at or above the reporting limit.
J	The identification of the analyte is acceptable; the reported value is an estimate.
MRL-2	MRL verification for Non-Potable Water matrix
MRL-3	MRL verification for Soil matrix

Appendix D – Generic RSL Calculations

Risk-Based Regional Screening Levels (RSL) for Soil to Groundwater

Key: I = IRIS; P = PPRTV; O = OPP; A = ATSDR; C = Cal EPA; X = PPRTV Screening Level; H = HEAST; D = DWSHA; W = TEF applied; E = RPF applied; G = see user's guide; U = user provided; ca = cancer; nc = noncancer; * = where: nc SL < 100X ca SL; ** = where nc SL < 10X ca SL; SSL values are based on DAF=1; max = ceiling limit exceeded; sat = Csat exceeded.

Sub-chronic toxicity values will be used where available. RfC and RfD references followed by 's' indicates subchronic value; RfC and RfD references followed by 'c' indicates chronic value.
